We purpose on this page to give a list each week of the more important and practical articles appearing in the contemporary foreign and domestic medical journals.

Abdominal section, Hall. Cin. Lancet-Clinic, Oct. 19, 1889.

A case of primary carcinoma of the vagina, Hawley. N. Y. Med. Journal, Oct. 19, 1889.

Aphorismen zur Diagnose und Therapie der Kehlkopftuberculose, Schnitzler. Intern. Klin. Rundschau, 6 Oct., 1889.

Bakterien und Krankheitsgifte, Bielger. Wiener Medizinische Blätter, 10 Oct., 1888.

Cas typique d'ostéomalacie chez une femme en travail d'accouchement. Pièces anatomique. Guéniot. Bulletin de l'Académie de Médecine, 24 Sept., 1889.

Concealed pregnancy, its relations to abdominal surgery, Van der Veer. Jour. of the Amer. Med. Ass'n, Oct. 19, 1889.

Chronic endocarditis, Delafield. *Ibid.*

Chrysotis æstiva, notes on the tongue of, Inckerman. The Microscope, Oct., 1889.

Cornée, sur la suture de la, dans l'extraction de la cataracte (avec 3 figures), Suarez de Mendoza. Recueuil d'Ophthalmologie, Sept., 1889.

Der nervöse Kopfschmerz, Schnetter. Medizinische Monatsschrift, Oct., 1889.

Drinking water for cities, the purification of, Chapin. Jour. Amer. Med. Ass'n, Oct. 12, 1889.

Des maladies catarrhales saisonnières (suite et fin), Kelsch. Arch. de Méd. et de Pharmacie Militaires. Oct., 1889.

De la fatigue dans ses rapports avec l'étiologie des maladies des armées en paix et en campagne (suite et fin), Constan. *Ibid.*

Dermatological therapy, some general suggestions in, Sherwell. N. Y. Med. Journal, Oct. 19, 1889.

Duodenum, primary malignant diseases of the, Whittier. Boston Med. and Surg. Journal, Oct. 17, 1889.

Die männliche Impotenz und ihre Behandlung, Casper. Deutsche Medizinal-Zeitung, 30 Sept., 3 and 7 Oct., 1889.

Difflugia urceolate, a note on, H. M. S. The Microscope, Oct., 1889.

Diphtheritic laryngitis, intubation for, Johnston. Cincinnati Lancet-Clinic, Oct. 19, 1889.

Ethical question, an, Solis-Cohen. Med. News, Oct. 19, 1889.

Erfahrungen über ein neues Eisenmangan-Präparat, Ascher. Deutsche Medizinal-Zeitung.

Ein Vorschlag zur Handgelenkresektion, Lauenstein. Centralblatt für Chirurgie, 12 Oct., 1889.

Erysipelas in children, the surgical treatment of, Seibert. N. Y. Med. Journal, Oct. 19, 1889.

Eye surgery, needless and annoying restraints in, Chisolm. Amer. Jour. of Ophthalmology, Aug., 1889.

Enormous fibro-cystic tumor of the uterus, a case of laparotomy, recovery, Werter. Columbus Med. Jour., Sept., 1889.

Evisceration, Prince. Jour. Amer. Med. Ass'n. Oct. 12, 1889.

Estudio sobre las enfermedades carhinclosas ; su pecuencia en Chile ; medidas higiénicas y preventivas que convendria adoptar y su mejor tratamienti. Boletin de Medicina, Marzo y Abril de 1889.

Forced respiration, Fell. Jour. Amer. Med. Ass'n, Oct. 12, 1889.

Fistula in ano, a simple method of treating, Mathews. Amer. Practitioner and News, Oct. 12, 1889.

Fever, on, Millikin. Cinc. Lancet-Clinic, Oct. 19, 1889.

Fever and antipyretics, Thorburn. Canadian Practitioner, Oct. 16, 1889.

Fadenpilze in der Nase, Schubert. Berliner Klinische Wochenschrift, 30 Sept., 1889.

Genu-pectoral or knee-elbow position in obstetrics, Wenning. Cincinnati Lancet, Clinic, Oct. 12. 1889.

Gonorrhœa, Lydston. The Med. Age, Oct. 10, 1889.

Galvano cautery in the treatment of hypertrophoid tonsillitis, Knight. N. Y. Med. Journal, Oct. 12, 1889.

Hæmatometra, Gross. Maryland Med. Journal, Oct. 19, 1889.

Histological technique of the blood (illustrated), Freeborn. The Amer. Monthly Microscopical Review, Oct., 1889.

Hernia in infants and children, notes on the causes and management of, Milbe. New Orleans Med. and Surg. Jour., Oct., 1889.

Hip-joint disease, Witherington. Memphis Med. Monthly. Sept., 1889.

Health Board, functions and duties of, Munn. N. E. Med., Oct. 18, 1889.

Intubation for diphtheritic laryngitis, Johnston. Cincinnati Lancet-Clinic, Oct. 19, 1889.

Iodides, on the alleged tolerance of, in the syphilides, Stelwagon. The Therapeutic Gazette, Oct. 15, 1889.

Jaborandi and pilocarpine in Bright's disease, Egan. The Med. Record. Oct. 19, 1889.

Is Senn's gas trust infallible and always devoid of danger, Dalton. Amer. Practitioner and News, Oct. 12, 1889.

Intestinal parasites, Ames. Columbus Med. Jour., Sept., 1889.

Intraoculare Erkrankungen bei Nasenleiden, Ziem. Berliner Klinische Wochenschrift, 30 Sept., 1889.

Laparotomy for invaginated bowel, Crymes. The Alabama Med. and Surg. Age. Oct., 1889.

Lungs, a pathological condition of the, hitherto undescribed in this country, but which is not infrequent, Porcher. Med. Record, Oct. 19, 1889.

Legal matters of interest to the physician, Riley. *Ibid.*

Labor, on the management of, Hosbrouck. Calif. Med. Jour., Sept., 1889.

Laparotomy for perityphlitic abscess unsuccessful, Kennedy. Canadian Practitioner, Oct. 16, 1889.

Malignant disease in Japan, report on the investigation into the. The Sei-i-Kwai Med. Journal, Aug., 1889.

Management of infants under a year old, hygienic, dietetic, and medicinal, Greenley. Journal of the Amer. Med. Ass'n, Oct. 12, 1889.

Modern medical science, Coe. N. Y. Med. Jour., Oct. 12, 1889.

Necrosing ethmoiditis, Donnelly. N. W. Lancet, Oct. 15, 1889,

Oleate of veratria, the employment of, to facilitate the determination of errors of refraction, Theobald. Amer. Jour. of Ophthalmology, Aug., 1889.

Ocular muscles, rheumatism of the, Wright. Columbus Med. Journal, Sept., 1889.

Oil of tansy poisoning, case of, Witherington. Memphis Med. Monthly, Sept., 1889.

Perineum, an easy method of repairing the, Da Costa. Maryland Med. Journal, Oct. 19, 1889.

Pregnancy and operative surgery, their mutual relations, Gordon. Boston Med. and Surg Journal. Oct. 17, 1889.

Pathology of the nervous system, recent progress in the, Knapp. *Ibid.*

Preventive measures against cholera, report on, Todanori. The Sei-i-Kwai Med. Jour., Aug., 1889.

Prescribing at names, Fearn. Calif. Med. Jour., Sept., 1889.

Painful muscular spasms after fracture perfectly controlled by sulfonal, Andrews. Jour. Am. Med. Association.

Pyosalpinx, some points in the diagnosis of, Hall. Cincinnati Lancet-Clinic, Oct. 12, 1889.

Pieds bots talus valgus guéris par le retressment manuel, observation de, et l'immobilisation dans l'appareil de guttapercha, Bilhaut. Annales d'Orthopédie, 1 Oct., 1889.

Papillomes des fosses nasales, contribution à l'étude (suite et fin), Lacoarret. Revue de Laryngologie, 1 Oct., 1889.

Proposed new lunacy law, Peterson. Med. Record, Oct. 19, 1889.

Periodicity of women, Bissell. California Med. Journal, Sept., 1889.

Pulverised testicle juices as at herapeutic agent, Reed. Journal of the National Ass'n of Railway Surgeons. Sept., 1889.

Posterior dislocation of both bones of the forearm, Fischer. Amer. Practitioner, Oct., 1889.

Primary Lithotomy in Russia, Idelsen. Annals of Surgery, Sept., 1889.

The convulsions of reproduction and their congeners, Archibald D. Macdonald, M. D. Medical Press and Circular, Sept. 25, 1889. *Ibid.*, continued Oct. 2, 1889.

Clinical Lecture.

(Delivered in the Pennsylvania Hospital, Oct. 5, 1889.)

BY THOMAS G. MORTON, M.D.,

Professor of Orthopædic Surgery in the Philadelphia Polyclinic; One of the Attending Surgeons to the Pennsylvania Hospital and to the Orthopædic Hospital, etc.

AMPUTATION OF FORE-ARM—REMARKS UPON TREATMENT OF WOUNDS.

THE first patient is a man twenty-five years of age, who was admitted sixteeen days ago: it is a case of machinery crush of the left hand and fore-arm. He was brought at once to the hospital, and amputation of the fore-arm, at about the middle, was done within two hours after the injury was inflicted. The dressings have not been removed nor disturbed since they were applied. As you see, they are perfectly dry and free from odor. There has been no suppuration. This is due to the fact that certain precautions were adopted in operating, and particular dressings employed. Those of you who were here last year know what these precautions and dressings are, and why they have been called "antiseptic."

Suppuration requires three conditions: moisture, warmth, and living organisms. Leave out any of the three, and suppuration will not occur. We cannot avoid warmth and moisture in such cases, but we can prevent infection by living organisms, and for this purpose we find nothing equal to bichloride of mercury in solution (1–2000 or 1–4000). It requires some care, of course, in handling a mercurial solution, and occasionally it affects a nurse or attendant, who has his hands frequently wet with it, but this can be easily avoided by ordinary care and prudence.

After the amputation, several strands of cat-gut ligature were left protruding from one corner of the wound, for drainage, and the flaps were brought together with cat-gut sutures. There are many kinds of drains in use, rubber, glass, and so on, but if we use a foreign body of this kind, we are obliged to open the wound earlier than if a gut drain is used, because a drain which cannot be absorbed prevents complete closure of the wound. Therefore, I prefer a drain of cat-gut, which causes no irritation and is finally dissolved and absorbed, after it has fulfilled its purpose; and the dressings may then remain undisturbed for weeks if desired.

The antiseptic treatment of wounds consists in a series of manipulations performed upon a part before, during and after the operation; and unless these are all carried out systematically and completely, it is not true antiseptic treatment. Partial antiseptic treatment is not antiseptic treatment at all; it is merely a pretence and a delusion. Unless you adopt the system in full, your results will be unsatisfactory, human life will be sacrificed and you will fail in your duty to your patients.

Although the stump has healed perfectly, except at the spot where the drain came out, we will re-apply the dressings as at first, using the wet bichloride gauze and iodoform, covered again by absorbent cotton as before. This will be worn a week longer. We would not have disturbed the dressings to-day, had the man not wanted to go home.

Immediate union is now the rule after amputations, it was formerly a rare exception. I have had it after amputations of thighs where I have not dressed them for three weeks following the operation, and with perfect recovery.

You notice that I place directly over the surface of the wound a piece of what we call protective; it is simply a piece of oiled silk, coated with copal varnish and dextrine. It is merely for the purpose of preventing the dressing adhering to the sutures, and as it keeps moist so allows drainage from the stump. By the use of this method we have union of wounds at once, which was almost impossible before the introduction of antiseptics into surgery. We now have immediate union of skin, cellular, muscular and fibrous tissue after amputations, just as readily as in simple incised wounds. Moreover, we used to have occasionally secondary hemorrhage after amputations, at the time when the ligature came away from the artery. Now, we avoid, by using ligatures that become absorbed, the dangers of suppuration and pyemia as well as secondary hemorrhage.

DISLOCATION OF THE FORE-ARM BACKWARDS.

This boy, ten years of age, has just come into the hospital with a recent injury to his arm, owing to falling from a box and striking his hand with some force upon the ground.

We have here a deformity of the right elbow, which is very evident when we compare it with the left one. There must be something here that is not right: either a dislocation or fracture, or possibly both. There is widening of the space between the condyles of the humerus, and the olecranon is not in its place. The arm is held nearly extended or only slightly flexed, and attempts to extend or flex it further produce pain.

The signs of fracture are abnormal mobility, crepitus and deformity. Very often in children a separation occurs between the shaft and the end of the bone which enters into the articulation—the epiphysis—as a result of violence like this, instead of an ordinary fracture. As I can trace the whole length of the ulna with my finger, such a condition does not exist in this patient.

In these cases it is always proper to administer ether and make a thorough examination and establish your diagnosis. I now find that there has been a dislocation of the bones of the fore-arm backwards and upwards, while the lower end of the humerus has slipped forwards.

It is very important to make a diagnosis as early as possible, because in the first place the diagnosis governs the treatment; and, secondly, because the difficulty of reducing the dislocation, rapidly increases with the lapse of time; moreover, it is easier to make the diagnosis before much swelling has taken place. Dislocations soon become old, and it may then be impossible to reduce them at all, because the parts have become rigid and the articulation itself affected by inflammatory changes, so that it would finally require an extensive operation with division of the lateral ligaments and fibrous bands, and even then we may fail to effect reduction.

By falling upon the open palm, the ulna and radius have been driven upwards and backwards; now, by reversing this and making traction and at the same time flexing the fore-arm and holding the humerus firmly with the other hand, the dislocation is at once reduced. Nothing is now needed beyond confining the arm in a bandage, and carrying it in a sling for a few days.

DOUBLE HYDROCELE—TREATMENT BY EXCISION OF PART OF THE SAC.

This man, 26 years of age, has an enlargement of the scrotum, which has existed for at least eight years. It is a hydrocele, a very common affection. In this case we find the swelling on both sides, which is not common. When we speak of hydrocele, we naturally think of it as it occurs in the male; but it may occasionally be found in women, making its appearance in analogous parts, in the inguinal canal near the round ligament.

Now, hydrocele consists in a collection of fluid in the tunica vaginalis testis, or the sheath of the spermatic cord, or alongside of the cord. It may be on either side or both sides.

Hydrocele, as it appears in the scrotum, presents us with a tumor more or less pyriform in shape, and more or less hard; the quantity of fluid may vary from a few ounces to a gallon. I have seen such a tumor extend to the patient's knees, and contain a gallon or more of fluid.

The diagnosis is easily made. All the disorders of the testicle may be excluded by taking the patient into a dark room, and with a candle attempt to pass light through the tumor. If it is perfectly transparent, it is a hydrocele, containing clear fluid, which is identical with the serum of the blood. Hernia is excluded by the fact that no impulse is transmitted to the tumor when he coughs.

In such cases there is often a history of injury to the part, or it may be caused by horse-back riding; it has been observed that cavalrymen are especially subject to it.

There are two plans of treatment—the palliative and the radical. The first consists in simply drawing off the fluid with a trocar, and repeating the operation as often as it re-accumulates. The radical operation has for its object the obliteration of the cavity by inflammatory adhesions. We may accomplish this by the injection of iodine, or some other irritant; the insertion of a seton, and leaving it in for twenty-four hours; or, by cutting down and removing part of the tunica vaginalis testis. One of the oldest methods was by injection, after removal of the fluid with a trocar. The older surgeons were very fond of the injection of port wine. But the tincture of iodine, full strength or diluted one-half with alcohol, has stood the test better than any other that has been proposed. This is thrown into the sac and, after being retained a minute or two, is allowed to escape. The caustic gives rise to violent irritation, congestion and inflammation, accompanied by the effusion of lymph, which occludes the sac and produces the cure.

We introduce the trocar in front, directing its point downward, so as to avoid striking the testicle, which is at the upper and back part. Sometimes the tunica vaginalis is greatly thickened, and it is exceedingly tough after the affection has existed for years. In such patients you will often fail with iodine. In this case I will perform the radical operation by excision of part of the sac, and will give him a little ether before beginning. I find upon incising the sac that the cellular tissue in its interior is quite œdematous, and we will remove this with the scissors. The fluid of a hydrocele is ordinarily clear; but it may be as white as milk, due to the presence of spermatozoa which have escaped into the sac.

When treating a hydrocele by injections, you should always be sure that it is not the congenital variety, for in such a case there is often a connection between the cavity of the sac and the general peritoneal cavity. In very young infants it is better to resort to external applications, such as painting with iodine, the application of pressure, etc. If you do inject, pressure should be made over the internal ring so as to prevent the passage of the fluid through into the abdomen, where it might cause peritonitis.

[The operation by incision, taking away part of the sac, and snipping off the œdematous cellular tissue, was repeated upon the other testicle, and the wounds brought together with three or four points of interrupted cat-gut suture, and dressed with protective, iodoform, and gauze.]

DIABETIC GANGRENE OF FOOT.

The next case is one of diabetic gangrene of part of the foot of a laborer fifty years of age—a colored man. We know that gangrene is going on here. The parts are discolored, devitalized, and have an offensive odor. Gangrene may arise from many causes. A heavy weight might fall upon the foot and crush it, and lead to loss of circulation and death of the part; but here is gangrene coming on apparently without cause. We find it associated with glycosuria, and we call it diabetic gangrene. It is a very interesting fact that patients with sugar in their urine are especially liable to gangrene, owing to local changes in the circulation. We know that it is diabetic, because the patient's urine responds to both the chemical and fermentation tests.

The gangrene affected the third toe of the right foot upon his admission; it now has extended to the fourth toe and part of the dorsum and sole of the foot. There is no line of demarcation forming. The propriety of an operation is questionable. We will merely remove the dead parts because the mass is putrefied and very offensive.

Dr. William Hunt, one of my colleagues on the staff of this hospital, has reviewed this subject in a paper read last December before the County Medical Society, from which I will make a few extracts.

In the first place, as to the diagnosis between this and senile gangrene, he observes that this is a moist, the other is a dry gangrene. As regards frequency, in forty-seven years the records of this hospital only show fifty-nine cases of diabetes altogether; from 1842 to 1848 there was not a case admitted; from 1858 to 1869 there was not a case admitted; and in the Philadelphia Hospital it is also rare, so that among the poor, diabetes is an uncommon affection. Dr. Hunt sent out queries to a few physicians of this city to ascertain the frequency of the complication. Thirty answers were received; of these seven respondents had seen no gangrene in diabetic patients, twenty-five reported sixty-four cases. The ages, where given, were: 1 between 30 and 40; 2 between 40 and 50; 11 between 50 and 60; 12 between 60 and 70; 10 between 70 and 80; 2 between 80 and 90. Of the sexes given, 24 were females and 25 males. Of social standing, where given, 16 were wealthy, 23 medium, 9 poor, and of the latter 6 were in hospital. The seats of gangrene, where reported, are lower extremities—below the knee 37, thigh and buttocks 2; nucha 2, external genitals in females 1, lungs 3, fingers 3, back 1, eyes 1. Among these, boils and carbuncles are not included. As to the mode of death, Dr. Hunt considers consumption as rather an accidental complication, and that the usual mode of death is by coma, œdema of lungs, or exhaustion. Emaciation is often entirely absent.

As regards the question of amputation, it is better to leave such patients alone; but it is justifiable to remove an offensive mass which makes the patient shunned by others. There is no line of demarcation, but we will attempt to secure healing here by immediate union, and will apply the usual antiseptic dressing. We find the bone separated from peritoneum and the tissue in bad condition. The third metatarsal bone is divided by the bone forceps at about its middle. We now pass a drain through from back to front, having scraped the wound with the curette to separate dead tissues. I show you here a new instrument, the douche-curette, having a hollow handle, through which a current of bichloride solution flows while you are scraping the surface, keeping the field of operation clean, and the spoon clear, thus enabling the operator to observe what he is doing.

Original Articles.

THE TREATMENT OF NEURALGIA.

By E. P. HURD, M.D.,

PROPHYLACTIC TREATMENT.

IDIOPATHIC neuralgia, like the other neuroses, is a hereditary disease. The ascendants of the neuralgic subject—one, or more of them—were either neuralgic, or were sufferers from hysteria, epilepsy, or some other neurosis; or, the parent may have impaired a naturally good constitution by intemperance or some other vice, and so entailed on the offspring that instability of nerve-organization which, under suitable provocation, finds expression in some form of neuralgia.

There are, of course, exceptions to the rule that neuralgia is a hereditary disease; children born healthy have had their constitutions undermined by insufficient diet, by some one or more of the diseases

peculiar to children (as scarlet fever or diphtheria), or even by precocious addiction to some vice, etc.

Children who have inherited the neuralgic temperament should not be allowed to study too hard at school, and should not be subjected to physical tasks of an arduous and exhausting nature. Moderation in all things should be the rule. Such subjects are unfitted to bear a strain. At the same time, they should be required to walk in the open air, to indulge in invigorating sports, to perform gymnastic exercises of certain kinds which can be borne without too much fatigue, to practise rowing, horse-back riding, swimming. The cold bath, or cold douche in the morning is a good auxiliary. All these hygienic measures improve the circulation and develop a strong muscular and nervous organization. Hydrotherapy especially toughens the integument and prevents the frequent occurrence of debilitating rheums.

To these means should be added a full, generous diet of meat, eggs, fish, milk, cereals, vegetables and fruits. Very many cases of neuralgia have been traced to a meagre and insufficient dietary. When we remember that neuralgia is essentially a disease of malnutrition, and that nerve substance is a conglomerate of richest animalized principles (phosphorized oleo-albumen), we see that we must place in the foremost rank of remedial agencies those means which improve or restore the nutritive functions.

Some of the worst forms of migraine, prosopalgia, etc., that I have ever seen were among the poor and ill-fed. For delicate, half-starved, children brought up in slums and crowded tenement houses there can be but little hope; out of these breeding-places of disease come multitudes of the hysterical, the neuralgic, the nervously shattered, who float about between the hospital and the alms-house.

The neuropathic child should be taught the necessity of plenty of sleep. Too much emphasis cannot be placed on this requirement. Eight, even ten hours sleep a day is not too much. Those predisposed to neuralgia should be compelled to go to bed early—between the hours of nine and ten every night, and all evening excitements should be forbidden. Among the latter should be mentioned the reading of dime novels.

As everything that favors the precocious development of the passions is bad, the evil influence of corrupt companions is to be depreciated and avoided by every possible means. It is, however, a matter of great difficulty for the parent or guardian always to avert such influences, for the cousin or class mate of the moral and "goody" sort is often the one who in secret instils the poison and corrupts the nature of of the child.

Doubtless the evils of masturbation, as practised by children, have not been too highly painted. The neuropathic child cannot be too early, too earnestly or too faithfully warned against the pernicious effects of this vice.

PROPHYLAXIS IN THE ADULT.

The adult, who, by faulty organization, by debilitating influences, by previous attacks of neuralgia, is predisposed to this neurosis, demands essentially the same prophylactic hygiene as has been above outlined. He should possess some light, healthy employment, and avoid occupations that involve arduous toil and great anxiety. Good, nutritious food at regular seasons should be eaten, and alcoholic and other stimulants eschewed; the neuralgic should also religiously refrain from smoking. These patients are prone to seek excitement, and often suffer a breakdown in consequence. One patient with whom I was acquainted, used invariably to experience a return of her megrim after going to an evening party or a ball. Such persons are uncommonly vivacious under excitement, and endure well the strain for the time being. They are, however, capable of using up in one evening's dissipation all their reserve force, and of bringing their nerve-centers into a state of unnatural erethism that weeks of rest may not calm.

The condition of these sufferers is often deplorable. Of fine literary and æsthetic tastes, they cannot long enjoy reading, artistic pursuits, etc., without paying the penalty in an attack of severe orbital or supra-orbital neuralgia. One of my acquaintances cannot read an hour consecutively without twinges of pain through his temples, which oblige him to desist. He regards himself as shut out from the best enjoyments of life; is gloomy and suicidal. Persons of this temperament need an especially fortifying regimen; of which life on the sea (yachting), in the woods, among the mountains, with absolute freedom from brain work, shall form the principal part.

Some writers (as Vanlier and Anstie), have found excessive religiousness a factor in the genesis of neuralgia; but doubtless an ardent espousal of the most gloomy theological beliefs is less harmful than the indulgence of depressing vices, or the cultivation of voluptuous appetites.

The same remarks that have been made about sleep, are applicable to the adult neurotic, who should have regular habits of sleep, and whose sleep should be long and sound. If he happens to be a poor sleeper, he should endeavor to woo tired nature's sweet restorer, by taking much exercise in the open air, and especially diverting exercises, by cold bathing in the morning, and the warm bath just before going to bed, with vigorous shampooing of the body, along with the sipping of a cup of hot water containing some mild cordial, as spirits of lavender, or even a little Cibil's Fluid Beef; this is far better than resorting to any of the ordinary hypnotics, as chloral and sulphonal, which are sure, in the end, to leave the nervous tonus damaged. It is only exceptionally that I would allow a neuropathic patient to apply to any of the so-called hypnotics for relief. Where a small dose of whiskey, or a glass of bitter ale will produce refreshing sleep, this is safer than chloral or a narcotic. Sometimes it makes a great difference what the victim of insomnia eats for her supper, and there are all sorts of idiosyncrasies in regard to this. Some persons will sleep better with a full, some with an empty stomach. To some patients your best prescription is a supper of hominy and milk; to others, a light lunch, or cup of beef tea on going to bed.

Above all things, the neuralgic invalid should have a mind at ease, for anxiety, care, worry, over-

mastering passions, are the greatest foes to healthful sleep.

As adjuvants to a cure, there are certain tonic medicines which deserve mention here: quinine, strychnine, iron, arsenic, and a very moderate amount of some of the fermented liquors, wine and beer. To the anæmic, iron and arsenic are especially useful; a good combination is the *iron, arsenic and strychnine pill*, furnished by a number of our pharmacists.

Fothergill's pill is a good stomachic tonic. Its formula is as follows:

℞.—Acid. arseniosi . . . . . gr. j.
Ferri. sulph. exsic. . . . . ℥ ss.
Pulv. capsici . . . . . ℥ j.
Pil. aloes et myrrh . . . . . q. s.
M.—Ft. pil. No. LX.
Sig.—One pill three times a day.

Or five minims of Fowler's solution may be associated with ten grains of bicarbonate of sodium and five of potassio-tartrate of iron in a fluid ounce of infusion of quassia, this dose to be given after each meal.

Arsenic is one of the best anti-neuralgic remedies that we possess. According to Anstie, it is especially useful in the visceral neuralgias. With arsenic, cod-liver oil may often be conjoined to advantage. More satisfactory results will be obtained from the pure oil, when it can be borne, than from any of the emulsions, of all of which, according to my experience, patients soon tire. Too much care cannot be taken that the oil shall be perfectly sweet and fresh.

A course of electric treatment (galvanism preferably to faradism), sometimes works well; both by calming the erethism of the nerve centers, and promoting the nutrition of the latter. The electrical treatment of neuralgia will claim especial consideration in another article.

Treatment of Diatheses which lead to Neuralgia.—Neuralgia is sometimes under the dominance of a diathesis such as gout, chlorosis, rheumatism, hysteria, diabetes. The treatment which is devoted to the diathesis is the proper treatment of the neuralgia.

Neuralgia of Toxic Origin—Neuralgia may be dependent on a poison in the blood; lead, mercury, arsenic, alcohol, malaria. Here the leading indications are: 1, to suppress, then antidote, then promote elimination of the poison; 2, as far as possible to protect the organism from the effects of the toxic agent, and palliate symptoms as they may arise. It is evident that when the proper antidote can be administered, this is the remedy *par excellence* for the neuralgia. In malarial neuralgia, for instance, quinine in large doses is indicated. In alcohol neuralgia suppression of all alcoholic stimulants should be strictly enjoined. In nicotinic neuralgia tobacco should be abstained from. In colica pictonum, the proper treatment of lead poisoning will also cure the neuralgia.

Reflex Neuralgias.—These neuralgias are due to a localized morbid state (of the uterus, kidneys, etc.) and the successful treatment of the suffering organ will cure the neuralgia.

Surgical means of cure.—Neurotomy, neurectomy and nerve stretching have all been practised for the cure of intractable neuralgia. Nerve stretching will be considered with sciatica, and neurectomy (which has given some brilliant results) under the head of prosopalgia.

Treatment of Neuralgic Paroxysms.—When in the presence of an attack of neuralgia, the first thing, of course, to do is to relieve the pain. It is desirable, if possible, to obtain analgesia without resorting to morphine. In many of the neuralgias, such as migraine and those of central origin, whether idiopathic or symptomatic, antipyrin often gives speedy, marked relief, fifteen grains being followed by complete disappearance of the pain. A repetition of the same dose in six hours, and a continuance of this treatment for several days, the antipyrin being given often enough to keep the pain under subjection, may be all that is required, the patient being as far as possible removed from the reach of causal influences. This is Germain Sée's treatment of the headaches of students, headaches which often oblige matriculates to suspend study for weeks or months. Acetanilid in half the dose of antipyrin may be attended with an equally good result, and the same may be said of phenacetine. Lately exalgine has come into favor in some quarters; it has been praised as an anti-neuralgic by Dujardin-Beaumetz and Bardet.

It is probable that where antipyrin fails none of these other medicines will succeed.

In my own practice I have seen good results from acetanilid in neuralgic headaches. In cervico-brachial, dorso-lumbar and sciatic neuralgia I have seen no benefit from any of these members of the "aromatic series." Citrate of caffeine and guarana are remedies from which much good may be expected in hemicrania, and always where the pain seems to be the consequence of nerve tire. The dose of caffeine is three or four grains, of guarana twenty grains.

The following prescription for which I am indebted to the late Dr. George M. Beard has given good results in headaches of almost all kinds:

℞.—Cit. caffein.
Carb. ammon. . . . . āā ℈j.
Elixir. guaranæ . . . . . f℥j.
M.—Dose, a teaspoonful every hour till the pain is relieved.

Some of my patients, delicate migrainous patients, keep a bottle of citrate of caffein econstantly on their toilet tables; a frequent resort to it keeps them free from headaches. I have never seen any harm result from the continuous use of this drug.

Aconitine in pills of $\frac{1}{200}$ grain, one pill every five hours till the supervention of the physiological effects, or till the pain disappears, sometimes has a charming effect in migraine and tic douloureux.

In face ache, especially when due to a decayed tooth, the tincture of gelsemium in five-drop doses every two hours is often followed by speedy subsidence of the pain. I have always found gelsemium in this dose to be a perfectly safe remedy.

Some practitioners have great faith in a full dose of quinine (fifteen grains) in neuralgias of the peripheral nerves, whether due to malaria or some other cause. I cannot say that I have ever found this alkaloid beneficial in neuralgic paroxysms, except where the attack was clearly of malarial origin. "Gross'" neu-

ralgic pills, in which quinine is combined with aconite, strychnine and morphine are, I think, chiefly of use as a prophylactic where attacks have been frequent.

As outward applications chloroform liniment, veratrine ointment, extract of belladonna rubbed up to a paste with water, spread on cloth and applied over the seat of pain, have had their advocates. No external means can be relied on. Anodyne embrocations are more useful when the pain is rheumatic than when it is neuralgic.

Hypnotizers claim to have accomplished wonderful results by putting the neuralgic sufferer into the hypnotic sleep, and assuring him that the pain no longer exists. As nothing is impossible *a priori*, and all things are to be believed on sufficient testimony, we have now adequate warrant for a certain faith in hypnotism as a means of cure. Bernheim's book on "Suggestion as a Therapeutic Agency" contains a number of instances of severe neuralgic and neuralgiform pains cured by hypnotic suggestion.

It will often happen that none of the above means are applicable to the case in hand, or, if tried, they have resulted in failure. There is nothing to do then, but to resort to a hypodermic injection of morphine. The tablet triturates of the pharmacists are very handy for this purpose. The commencing dose should be the sixth of a grain. If no relief is obtained, the injection may be repeated in fifteen minutes or half an hour. In bad cases of tic douloureux, migraine, visceralgia, I have often had to repeat these injections every half hour until a grain, a grain and a half, and even two grains have been administered. Some pain creates great tolerance of morphine. I have seen a delicate neurotic girl in a paroxysm of cervicobrachial neuralgia bear with impunity a quantity of morphine introduced subcutaneously that would have killed a strong, well man. There is not the same tolerance of atropine, and it will not do to push the injections of this alkaloid. If for the first injection one of the morphine and atropine tablets be used, in the subsequent injections the atropine should be omitted. The dryness of the mouth and throat that follows a full dose of atropine gives the patient great annoyance and discomfort.

For ordinary hypodermic use I employ a solution of morphine, consisting of four grains of sulphate of morphine to a fluid ounce of cherry laurel water. Of this, a hypodermic syringe full may be injected with safety in an adult. The cherry laurel water keeps the solution from spoiling.

Inject into a fleshy part of the arm ; there is no advantage in injecting over the seat of the pain.

Deep injections of chloroform sometimes as effectually relieve the pain as morphine injections. For sciatica take up a syringeful of pure chloroform and inject it the depth of the syringe-needle into the gluteal muscles.

Antipyrin may also be used hypodermically. Dissolve eight grains in a hypodermic syringeful of warm water and inject the whole into a fleshy part of the arm or thigh. Germain Seé highly commends this use of antipyrin.

Oxygen is of value in neurasthenia.

HEROIC DOSE OF CHLORAL.

By A. C. FREE, M.D.,
HARRISBURG, PA.

IF the following case is half as interesting to read about as it was to those concerned in it, the writer will be amply repaid for his trouble.

In the fall of 1881, Mrs. S., living in the First Ward, Harrisburg, was seized with convulsions while entertaining some friends. Upon responding to a hasty summons, I found the patient to be a plump, short-legged woman, aged twenty-six. She was six and a half months gone in her first pregnancy. Two weeks prior to the first convulsion she had received a severe blow on the abdomen by falling over the edge of a tub. Life was extinct in the child, and of course it was expedient to get rid of the contents of the uterus. The consultant in the case made the prognosis of death within twenty-four hours, because the urine was loaded with albumen. I could not concur in the opinion on those grounds, because neither at that time nor subsequently has my experience warranted such a conclusion. The acceptance of that theory would have signed this woman's death-warrant, figuratively speaking.

There were no labor pains, the mouth of the uterus was high in the pelvis and closed, as in an ordinary primipara at six months. No medicines could be given by the mouth, for the reason that when the patient was not writhing in convulsions, she lay in a deep stupor. To accomplish the delivery it was necessary to insert the hand into the woman's capacious vagina, and by using bimanual manipulation open the uterine canal. This was most exhausting labor. After two hours' work, the severe strain and cramped position made a long rest grateful when the hand was finally inside. The rest of the operation was easy as soon as the hand recovered from the paresis caused by the violent muscular effort. It is terribly disagreeable to have to sit by a bedside with an aching hand and arm inside a female's genital organs for so long a time. The only redeeming feature about it is that it affords an excellent opportunity to study the physiological action of warmth and moisture.

Much benefit was expected to result from the removal of the uterine contents, but no immediate result was apparent so far as increasing the woman's chance for life. The cause of the eclampsia did not have a total inhibiting effect on the uterus. Central functional activity was still marked enough to stop, with the aid of pressure, a troublesome hemorrhage. By grasping the fundus above the symphysis and digging the fingers deep into the abdominal walls, and holding on, the desired result was obtained. Some delicacy in regard to using such strong pressure had to be thrown aside ; but even at the expense of dislocating some of the viscera or rupturing a ligament, the deed was done. With an empty and contracted organ to deal with, the convulsions persisted, and how to manage them became an important question. Every means at command was tried, but the patient grew worse, instead of better.

Finally, after much anxious deliberation, it was resolved to try the effect of ninety grains of chloral

hydrate by the rectum. Such a dose was regarded as heroic and dangerous, but the patient was in extremis. One hour afterwards the convulsions had not been repeated, but the pulse was becoming thready and almost imperceptible, and respiration was performed in gasps at long intervals. An ominous rattle in the throat made the outlook gloomy, and in addition to anxiety peculiar to such an occasion, the thought of being the direct cause of death tormented me. I had before this time unqualifiedly condemned a practitioner for yielding to a woman's demand for ether in confinement and then justifying himself when his patient died of ether shock. However, it was no time to be timid, and believing from the woman's looks that it was possible to pour a stimulant down her throat, two ounces of whiskey and twenty grains of quinine were used in the attempt. It came near finishing the career of the woman in short order; but, in spite of a fit of strangling, it was retained. In twenty minutes the pulse had gained perceptibly in strength, but the breathing was the same. Two ounces more of raw whiskey were poured into her, and when an interval of half an hour seemed to make no difference in her condition, I went home and went to bed at 11.30 P. M.

The conviction that there was no chance of recovery had fastened itself upon me, and yet, in spite of the fact that I had already been with the woman for two days and nights and was physically exhausted, it now looks as if I ought to have known that a halt in the disease when the patient was almost moribund was a great gain; but the truth is that, after making such a game fight, I was at home and asleep when the change came. Early the next morning a messenger rang the bell to know if Mrs. S. could have a drink of water. A few minutes later she was found in a semi-comatose state, asking for water every minute or two. Her mouth was as dry as anything could well be, the mucous lining of the buccal and pharyngeal cavities was glazed and shining, and on the tongue was a dark brown coating, which was cracked and fissured. Little jagged points, hard and sharp, stuck up all over its surface.

At eight o'clock, A.M., the woman opened her eyes and commenced to talk rationally. It was still the opinion of the consultant that death would be the inevitable result; but it did not turn out so, for she made a recovery, and has since been delivered of two children without trouble of any kind.

CONSTIPATION.

Abstract of a Clinical Lecture delivered at the Medico-Chirurgical College of Philadelphia.

By WILLIAM F. WAUGH, M.D.

IN the group of cases presented to you to-day, you will notice that constipation has been a feature of each, though they differ widely in their nature and in the other symptoms. You may judge from this how general is this aberration from health; so general, indeed, that the inquiry into the condition of the bowels forms one of the routine duties of the physician. It has been said that no visit is a strictly professional one unless the doctor looks at the tongue, feels the pulse and inquires about the bowels. I once heard a physician give as the reason for his popularity among his Irish patients, that he was never consulted for any case but that he first ordered a brisk cathartic, no matter what the nature of the disease might be. And though we very properly condemn such a practice, it must be acknowledged that it has far more to be said in its favor than most of the other routine practices, such as bleeding, cinchonizing, pepsine giving, tonic tippling, making vaginal examinations, etc. In fact, a very large proportion of the medical practice of every age has consisted of routine work for which it would be difficult to find as good an excuse.

In the treatment of constipation *per se*, apart from that of the conditions with which it is associated, there has been a marked change in modern methods. It is now fully understood that something more is needed than simply producing alvine discharges; which gives relief, but does not cure constipation. The use of the old-fashioned cathartics has become very limited, since it is learned that they exhaust the susceptibility of the bowels and increase the tendency to constipation.

As neglect is, after all, the prime cause of constipation, so the essential condition for its cure is the enforcement of regularity in resorting to the water-closet. The influence of habit is what our therapeutics is designed to obtain. Sometimes this is best done by adopting some means whose oddity serves to impress the mind of the patient. A buckeye carried in the pocket, a black ring on the finger, an odd pendant for the watch chain, may serve to remind the patient of the affection for which it was prescribed, and of the means of cure. I have succeeded in accomplishing this object by directing the patient to keep his cigars in the water-closet and to smoke only while at stool. It is necessary that when the patient goes to the closet he should have a reasonable certainty of securing an evacuation; and for this reason nature must at first receive artificial aid. For this purpose there have come into use, during the last ten years especially, a number of laxative pills, combining in various proportions aloes, nux vomica, belladonna, and sometimes other drugs. Nearly all manufacturers of pills send out such combinations, and many physicians employ favorite formulas of this sort. I add capsicum to the above-named ingredients, and yearly prescribe these pills in many cases. The essential ingredient is aloes, though this does not do as well alone as in combination. The dose should be the smallest which will suffice to produce the effect. And even then, as the influence of habit becomes stronger, the dose which is at first requisite will be found to be too large, and can be reduced gradually until finally it can be dispensed with entirely, and the cure is complete. To secure the true tonic effect of this combination, the daily dose should be divided into three parts, one to be taken after each meal. As the patient improves the doses should be decreased in size, but not in number, the three daily doses being given in constantly lessening quantity until they become almost infinitesimal.

For all ordinary forms of constipation this treat-

ment is quite satisfactory. But it will not answer when there are hemorrhoids, rectal ulcers or menorrhagia; nor when the condition is rather one of costiveness with an abnormal dryness of the intestinal contents. In the latter case aloes in the smallest doses will cause great distress and painful cramps, without affording relief. The object is not stimulation of peristalsis, but of the intestinal secretions. This can be obtained by the administration of hydrastis, the saline laxatives, or chloride of ammonium. But the best remedy by far, one that has here no rival, is cascara sagrada. I may add that this is the only form of constipation in which cascara is really superior to other drugs, or, in other words, is truly indicated. It also should be given in the smallest quantity which will give relief, and preferably in a single daily dose after breakfast. It may be given in the form of fluid or solid extract, but the best formula is the fluid extract combined with the extract of malt. The latter seems to enhance the value of cascara, five to fifteen minims in malt extract having as certain an action as a drachm given alone, and with less griping. This is the case even with malt extracts which are not themselves laxative.

So comprehensive is the range of these two medicaments that you may practise a long time before you meet with a case in which they fail. When you do, you can at once inform your patient that there is a mechanical obstacle in the way, the nature of which can be ascertained by a local examination. It may be a retroverted uterus, rectal stricture or polypus, or some form of pressure from without; against any of which the best regulated diet and laxatives will be as powerless as the brisker cathartics, though not so injurious.

MEASLES IN THE SECOND WEEK OF INFANCY.

By T. RIDGWAY BARKER, M.D.,
Demonstrator of Obstetrics and Assistant in Clinical Surgery in the Medico-Chirurgical College, Philadelphia.

APPRECIATING the fact that measles is of rather infrequent occurrence at such an early age, I feel justified in reporting the following case somewhat in detail.

A. G., aged two weeks, found, on my first visit, to be a small, weak, imperfectly-developed female infant, with a feeble circulation, indicated by the cyanotic hue of the skin. The child nursed poorly, though the mother furnished an abundance of milk.

The birth occurred at full term. The mother, a multipara, was attended in her confinement—which came on unexpectedly and proceeded without difficulty—by a neighbor (it was deemed unnecessary to send for a physician, so speedily was the woman delivered).

The good neighbor thus hastily called in quite forgot, in her excitement, that the children of her own household were convalescent from measles. The infant, as already mentioned, had inherited but feeble vital powers, and, on further examination, it was very evident that there were in addition certain morbid principles at work.

The skin was hot, dry, and congested; the eyes half closed; a weak, stifled cry was emitted at intervals. The fecal discharges were green, fetid, and slimy. No eruption was present on the extremities or trunk, though diligently sought for, nor was there any indication of broncho-pulmonary catarrh. The treatment was directed to correcting the catarrhal condition of the alimentary canal, by increasing secretion and hastening the removal of the products of fermentation.

Calomel in one-twentieth grain doses every two hours was administered.

On the following day there were signs of improvement, the discharges being no longer green and fetid. The temperature remained elevated, however, and in addition to the symptoms common to the febrile state there was a short, hacking cough, bronchial in character. The same treatment was continued, with the administration of sp. æth. nitrosi, ten drops every hour.

At my next visit (fourth day) the whole body was covered with a measly eruption. It was slightly elevated; in crescentic blotches, with intervening unaffected patches of skin—in a word, it was the unmistakable eruption of measles. The cough became more persistent and disturbed the sleep. The dose of the calomel was increased to one-tenth of a grain every two hours, and the sp. æth. nitrosi to twenty drops every hour. This treatment was continued for two days, when the eruption began to fade and the skin to assume a more natural appearance. The cough, which proved very intractable, greatly interfered with nursing and taxed severely the patient's strength. For the relief of this source of annoyance hot applications and mild counter irritation were employed. On the ninth day the eruption had quite disappeared and desquamation was apparent, though slight. The child's general health rapidly improved and it was soon completely recovered.

It would seem but reasonable to conclude from the history of this case that the infant became infected at the time of delivery.

1. There had been no case of measles in the immediate family, though several of the children had never had the disease.

2. The period of incubation was about ten days.

3. The time of the breaking out of the eruption was characteristic.

All these factors, I think, point most conclusively to the view that the affection was contracted from the midwife.

Fortunate, indeed, was it that the bronchial symptoms were mild, for had they been otherwise a fatal termination would have been almost inevitable. While the case may be considered in many respects a typical one, it is not uncommon to meet with those whose views would widely differ. In fact, it appears that each epidemic has certain well-marked peculiarities.

At one time, as in the epidemic of the winter of 1887, the bronchial inflammation assumed an exaggerated form, and then the mortality increased in a direct ratio. At another, the character of the eruption underwent a change—either in resembling

that of scarlatina, as pointed out by Rush, or in being tardy in its appearance.

While in the vast majority of cases the eruption appears first on the face, it does not uniformly do so. It sometimes breaks out first on the trunk or extremities.

Diarrhœa has occasionally been a concomitant symptom in certain epidemics, especially so in the epidemic reported by Rush in 1801.

The same author further noted that there were cases in which there were "decided remissions and intermissions—as in the autumnal fevers." It is probable the temperature was influenced by a malarial taint in the system.

To briefly summarize, then, the clinical history of measles: In the main the characters of the symptoms are constant, yet they are not always so—variability in location, extent and appearance of eruption, as well as deviations from the standard course, being not at all infrequent.

FIFTY-THREE SUCCESSIVE OVARIOTOMIES, WITHOUT A DEATH.

THE above statement was made in reply to a visitor to Dr. Mundé's clinic, October 30, 1889.

Lacerated Cervix—Emmett's Operation.—I leave the sutures, in some cases, for a much longer period than is customary; in fact, have left them until after the approaching menstrual period. I can see no practical objection to this procedure.

Lacerated Perineum—Tait's Operation.—This operation may be made for complete or incomplete laceration. It is extremely simple and thoroughly effective in its results. Of late I have used it in all my cases of uncomplicated, complete and incomplete laceration of the perineum. I have, since October, 1887, operated by this method seventeen times—eight complete, nine incomplete—with sixteen successful cases, and one death from septicæmia. (For complete account of operation see *American Journal of Obstetrics*, July, 1889.—K. B. P.

ROOSEVELT HOSPITAL, NEW YORK.

REMARKS ON CASE OF STRANGULATED HERNIA.

THE case of strangulated hernia, on which I operated last week, and in whom we made a resection of the gut, approximating the lateral surfaces of the gut by use of Abbe's rings, died on Thursday. I mentioned at that time that he was suffering from chronic alcoholism, and was therefore a very unfavorable case. The autopsy revealed a very interesting fact. There was not the slightest adhesion between the approximated peritoneal surfaces, although death occurred at the end of nearly 120 hours. The cause of death was septic peritonitis.

EXCISION OF JAW FOR SARCOMA.

This man, aged seventy, had trouble with his jaw twelve years ago. Cause supposed to be carious teeth. A few years after, he noticed a swelling on the right lower jaw, which has steadily increased in size since that time, and is now so large as to interfere with deglutition. Our diagnosis was "fibro-sarcoma" of the jaw, and was sustained by microscopic examination. The age of the patient is an objection to operation, but the condition is such as to warrant operative measures. I shall make an incision along the edge of the jaw from the symphysis to the angle, thence to the neck, divide the jaw through the symphysis, and turn it out from the socket. We have now made our incision and sawed through the jaw, but the tumor is so friable that we will not be able to turn the jaw out of the socket, but will have to dissect it out. To close the wound the mucous membrane of the cheeks will be sewed together, and the oral cavity closed off. The wound will be packed with sterilized gauze. The patient will be fed by the stomach tube for some time.

Radical Cure for Hernia—McBurney's Operation.—This man has an indirect inguinal hernia, which prevents his working. I shall open up the sac, return the intestine, sew the neck of the inguinal canal together, close the internal ring by suture, invert the skin by means of sutures, lessen the width of the wound by lead plate tension sutures, two will be sufficient, and pack the cavity left by the inversion of the skin with iodoform gauze, then the outside dressing. The man should make a perfect recovery.

—K. B. P.

MEDICO-CHIRURGICAL HOSPITAL.

UTERINE CANCER.

I PROPOSE to bring before you a woman who is suffering from cancer of the uterus. She now has tenderness, marked pain, discharges and frequent hemorrhages. A few years ago her physician found the affection to be malignant and curetted the diseased surfaces, but did not use any other treatment of importance. Pain is not always a necessary factor in cancer of the womb. The reason cancer appears mostly in the cervix is that the latter is so located that it is most likely to suffer from injuries in parturition and is consequently liable to be the seat of a degeneration. Cancer starts in the body of the uterus in only two per cent. of cases. The malignant cancers may be carcinomatous, encephaloid or epithelial—the latter are the most common. The disease is not frequent in the unmarried. Where laceration of the cervix has once occurred there is thrown out an inflammatory exudation of low vitality, and on account of coition, rubbing and irritation, this tissue is kept irritable, finally taking on malignant degeneration.

In the patient before us there is evidence of infiltration of the uterus, with nodules in the vagina.

The operation I propose to do to-day is simply for the purpose of prolonging her life and not of producing a cure. By scraping away the tissue that is breaking down we may afford her an opportunity to regain her health for a time. By the stoppage of the hemorrhage and removal of the broken down tissues these patients rapidly regain their appearance of health. In an operation of this kind the best instrument to use is the finger, as you can determine the amount removed. The tissue breaks down readily under the finger, and we can reach into the body of the organ, showing that it is diseased also. We must take great care not to break open the bladder or rectal walls, for they are so fragile and delicate, and either would be an unpleasant complication. I will use the curette from the end of which flows a stream of water.

There are three kinds of tissue here. 1. A layer that breaks down under the finger, the bloodvessels of which are dilated, thin, and rupture easily. You must be careful in digital examination and in the use of the speculum. 2. A layer infiltrated with cancer cells that is as dense as the skin. From this the disease will re-develop in a few weeks or months, and give rise to similar symptoms. To give relief you must get beyond this. 3. A zone containing only a few cancer cells. To produce a cure you must pass beyond this to the healthy tissues. One plan used to be to amputate the cervix, but this is not satisfactory, as you do not know how much to cut away. Sims' plan is the one I have adopted this morning. Scrape away the first or soft zone and arrest hemorrhage. In forty-eight hours wash out the uterus and apply tampons of cotton soaked in a solution of chloride of zinc, ʒvj to aquæ ʒj. If the walls are much thickened you may use an ounce of the zinc. In a few days the tissue becomes white, dense and hard; a slough forms; by continuing this process you have a mere shell of the organ left or even the whole organ itself may be removed. Complete removal of the organ is the most certain means of relief where the other organs are not affected or involved.—*Montgomery.*

Gastric disorders are frequently attended with a numbness of the arms. When there is a deficiency of gastric juice, as in dyspepsia, the use of liquids should be diminished; as they dilute the juice to an injurious degree when taken in the customary quantity.—*Woodbury.*

For multilocular sclerosis Woodbury prescribed as follows: 1. Zinci phosphatis, gr. $\frac{1}{10}$; ext. belladonnæ (alc.), gr. $\frac{1}{4}$; ext. nucis vom., gr. $\frac{1}{6}$; ft. pil. No. 1. Sig.—Thrice daily. 2. Cod liver oil and 3 grs. of Vallet's mass; thrice daily. 3. Hygiene: open air, avoidance of over-exertion. Patient is doing well.

PENNSYLVANIA HOSPITAL.

ENUCLEATION OF THE EYE-BALL.

MORTON presented the case of a Pole threatened with sympathetic ophthalmia. The ball of the injured eye was an inflamed mass—panophthalmitis—and beyond all hope of restoration to usefulness. To save the yet unaffected eye the doctor deemed enucleation of the affected eye, not only to be advisable, but a necessary procedure. Preliminary to the operation he remarked: "It used to be the custom among surgeons, when enucleating an eye-ball, to plunge the knife into the orbital cavity, and with a circular sweep, practically denude the cavity of its entire contents. To-day that is not done. We are careful to leave the conjunctiva and muscles of the eye-ball, that they may furnish a cushion-like support to an artificial eye, and giving the person possessing one nearly as much control over it as he had over his natural eye. I shall dissect free the conjunctiva at the margin of the cornea, and will then pick up each muscle with a tenaculum, and sever it at the point where it is inserted into the eye-ball. After I have the ball free from its attachments, I will pass a pair of curved scissors beneath the ball and sever the optic nerve close to it, being careful not clip off with the nerve any of the sclerotica to act as a foreign body, and so set up further inflammation." The operation being done, the lecturer further remarked: "After an operation of this kind it is not well to use styptics, such as the sulphate of iron, that control hæmorrhage too rapidly. The vessels in the orbital cavity which communicate with the brain are liable to give rise to serious complications when too quickly clogged. Better use pressure or cold."

PHILADELPHIA HOSPITAL.

VERSION BEFORE LABOR.

DR. HIRST brought before the class a woman who expected to be confined in a week or ten days, and diagnosed the position of the fœtus as that of a breech presentation. As the death rate is much greater in breech than in normal head presentations, it was recommended to convert the former into the latter, before the breech is engaged in the pelvis. All that is necessary is to manipulate the fœtus gently and gradually turn it round as in this case, until we have converted it into a head presentation—right occipito posterior or anterior. Great care must be taken not to rupture the uterus by rough manipulation. A binder was applied to the woman and she was instructed to remain in bed; since the fœtus had a tendency to resume its old position.

CYSTITIS COMPLICATING PREGNANCY.

This is a frequent, troublesome and dangerous complication of pregnancy. The lecturer had a case of cystitis last year in which the inflammation extended to the kidneys and caused death. Post-mortem examination showed that the kidneys were mere sacs of pus. In the course of the disease, if fever arises, there is pain in the back and pus in the urine, we must look to the kidneys. On the first day after labor this woman's temperature rose to 101°, with pain, inability of the bladder and pus in the urine. On the second day temperature was 102°. After the first course of treatment the temperature fell and to-day she is practically well. A one-half of one per cent. solution of creoline was used to thoroughly irrigate the bladder. It is one of the most favorable disinfectants and antiseptics to use on mucous membranes. Care was observed in regard to diet and absolute quiet and rest enjoined.—*Hirst.*

ELECTRICITY IN GYNÆCOLGY.

THE time has not yet arrived for the complete settlement of the controversy between gynæcological electrotherapeutists and operators. The warfare in many respects is an unequal one. Surgery has, without doubt, attained a high degree of success in this particular department; but it must be remembered that it has only reached this success after a long period of many failures; that in the beginning it was regarded with abhorrence by many of the highest living authorities—just as innovations of the same sort are now regarded; that it is of itself a fascinating and brilliant field of medicine, particularly so to the younger generation, thus rendering their opinions more or less partial; and finally, that it demands more than average skill and facility for the accomplishment of its highest results. On the other hand, electricity as a therapeutical agent in gynæcology is of comparatively recent introduction; is slow in its operations, and entirely void of that éclat necessary to render it universally popular; is expensive, and still amenable to greater improvement; and, in fine, requires for its successful operation more than the average knowledge of the electric force and its laws.

As we have said, it is too early yet to come to any positive decision as to the comparative merits of electricity and surgery in the treatment of uterine diseases. In the majority of instances no comparison is at all possible, for there are cases which can only be relieved by the knife, and there are others in which electricity affords undoubted cure without a resort to surgical measures. But comparing the treatment by electricity with that by the knife, when the latter was of the same age as the former, we cannot see that it presents so bad an appearance or promises so unfavorable an outlook. It is to be regretted that there is not as much enthusiasm, earnestness, and extensive trial of the electric treatment as there is of the surgical; other reasons, in addition to those we have already enumerated, are, doubtless, fully explanatory. It is unfortunate that electrotherapeutists have not yet the same array of statistics and do not generally keep the same close record of their results as do the surgeons; but time, perhaps, will bring about a change in this respect more to the credit of electricity. In the present contest there is not a little exaggeration and unfairness on both sides, and it is to be hoped, for the sake of true science, that all personalities and acrimony will be entirely left aside and that a calm, critical study will be adopted as the only guide to the proper solution of the entire question.

For the third time the subject was brought before the British Medical Association at its last annual meeting, held at Leeds, August, 1889. An animated discussion was the outcome; but we cannot help remarking the fact that those who were the most hostile to the use of electricity seemed to have had the least experience with it. Their objections were largely of a theoretical nature. As Dr. Playfair said in his opening paper: "If merely theoretical objections could prove that a really good thing was useless, we should at this moment be without railways or telegraphs; or, to take examples from medicine only, without ovariotomy or anæsthesia, for were not all of these condemned as impracticable or so dangerous as to render their use inadmissible?"

In the absence of complete statistics showing the results of electrical treatment in gynæcology, few would care to go so far as Keith and say that a man who performs a hysterectomy or an oöphorectomy for a hemorrhagic fibroid before trying the hæmostatic effect of electricity is guilty of a criminal offence. On the other hand, one would certainly be blockading the advances of science who, like Tait, assumed a direct opposition to the new method without allowing it a sufficient test and trial.

In certain affections of the endometrium, such as uterine catarrh, chronic endometritis, and membranous dysmenorrhœa, the application of the negative current through the insulated intra-uterine sound produces the happiest results.

According to Engelmann the use of the same current is advantageous in promoting the absorption of chronic inflammatory exudations in the pelvis. In regard to this, however, there is considerable difference of opinion among observers, a fact which may be due somewhat to the high intensities recommended and used by so small a number of electrotherapeutists. In regard to the removal of uterine fibromata opinions vary. Scarcely any electrotherapeutist claims that the current will cause a complete disappearance of the tumor; but if the annoying symptoms are made to disappear and the hemorrhage checked, what more can be asked of any method of treatment? In many instances there is undoubted diminution in the size of the growth, whether this be due to direct

absorption of the abnormal elements or to stimulation of the surrounding tissues, which of itself brings about a condition of pressure and anæmia and so a destruction of the tumor. In a large majority of the cases, though the tumor is not entirely removed, there is no return of the symptoms, and the woman to all intents and purposes is cured. Surely such a result when attainable should be accomplished in almost any way less dangerous than hysterectomy. No matter how expensive or tedious the method may be, requiring, as Keith says, twenty and thirty sittings on an average, it should be given a fair trial in each individual case before resorting to the more heroic measure however brilliant the latter may seem.

There are many questions yet to be settled in regard to this method of treating uterine fibroids. Some hold that only tumors of the posterior wall are amenable to the electrical treatment, and that it is useless to attempt to remove those of the anterior wall, or multiple tumors in this way. In some cases acupuncture, always with gold or platinum needles, will give the best results; in other cases simply the passage of the current through the tumor with the aid of the uterine sound is all that is necessary. The strength of current employed, the time of each sitting and the number of sittings required are some of the points still at issue. The majority of observers prefer mild currents, though Engelmann has given as high as 250 milliamperes. The sittings should not be longer than a few minutes each, once or twice a week; and after each sitting the patient should be kept in bed for a time. Upon all these points there will doubtless be for a considerable time yet a difference of opinion, but with the increase of statistics there will be found an average applicable finally to all cases.

In regard to the use of electricity in extra-uterine gestation, there can be no question as to its efficacy provided a positive diagnosis be made. Given a case of positive ectopic gestation, the only rule is to destroy the fœtus, and for this purpose no agent can compare with the electric current. We must admit, however, that electrotherapeutists seem to us to have diagnosed extra-uterine pregnancy rather more frequently than statistics would seem to warrant. It is not an easy matter by any means to differentiate such a condition from inflammation or abscess of the broad ligament, pelvic hæmatocele, tumors and cysts of various sorts, and as any of these conditions might be relieved by the electric current, the diagnosis of ectopic gestation would still remain in doubt. Since laparotomy is always available for the relief of this condition, it would do no harm and possibly some good to first try the electrical treatment. It should be remembered that the electrical treatment does not mutilate a woman, and therefore has this strong point always in its favor.

After all we need more serious, conscientious study of the uses of electricity in gynæcology. This new agent is undoubtedly one for good, if properly applied, and no amount of mere theoretical considerations on the part of objectors will prevent its universal adoption. The names of such men as Sir Spencer Wells, Playfair, Keith and Martin are so strong an endorsement that there only remains for the method the question of greater improvement.—L. H. M.

THE WILLIAMSON SCHOOL.

AS we predicted some months ago, the Trustees of the Williamson School have elected as the chief executive of that institution Passed Assistant Engineer Robert Crawford, U. S. Navy. The selection has received very favorable comments from the press of this city, where Mr. Crawford is held in high estimation for the good work done in the Spring Garden Institute, and later in organizing the Manual Training School. He will resign from the Navy and devote himself to developing the plans of Mr. Williamson. No better choice could have been made; and the trustees have shown such good judgment as, with Robert Crawford at the helm, bids fair to overcome the great difficulties which beset the way for Mr. Williamson's beneficent scheme.

It may not be amiss here to call the attention of trustees of educational institutions to the fact that in the army and navy there are to be found numbers of men who might be secured as teachers, and who possess exceptional qualifications for such positions. These men are finely educated; many have had experience as teachers while detailed for that duty at West Point or Annapolis—than which no finer schools for boys can be found. The discipline of the service has taught them how to exact obedience best.

In times of peace the services present little of interest to the most active intellects, and it will be recalled easily that many of our most distinguished officers were men who, like Grant and Sherman, had received their education at West Point, and then left the army, to return when the war broke out. Many officers in the army and navy to day would welcome an opportunity such as is offered to Mr. Crawford, but remain in the service through an exaggerated fear that they would not be able to win a living—a fear which is only intelligible to those who have been accustomed to the security of income possessed by these men. Patriotism is an unnecessary virtue in times of peace; the romance connected with the uniform soon wears off; and when one has a wife and family, long voyages or frontier forts cease to be enticing. And thus, in comparative idleness, the best men in the services rust away when there are hundreds of positions in the hands of inferior persons, for which these officers have exceptional qualifications, and which many of them would gladly accept.

THE report of St. Mary's Hospital Dispensary for the month ending October 31, shows that 407 new patients were treated and 1212 old cases were handled, making a total 1619 patients treated during the month.

Annotations.

IODOFORM oil injections in tuberculous bone and joint affections have been applied in the surgical clinic at Bonn, under Prof. Trendelenburg. The results were surprisingly favorable.

Iodoform oil, 5-25, freshly mixed before using, is injected into the diseased tissues at different points every eight days, after careful disinfection of the skin. Two to three c.c. are thrown in with considerable force by a hypodermic syringe, having a pretty large canula. Abscesses are evacuated by puncture, prior to injection. Injection into fistulous canals is not so useful as when the fluid is thrown into the neighboring structures. The parts are dressed with sublimate gauze. After three or four injections (sometimes more) the pain is diminished, the swelling begins to subside and become more firm, the abscesses become smaller and soon disappear. The fistulæ are most obstinate; but they yield to prolonged treatment. During the latter part of the treatment passive motion should be made. Complete fixation of points is only necessary in the beginning to overcome pain. Many cases are treated as out patients. The result, though not always favorable, is encouraging, because even in those who are only improved locally the general improvement is notable.

Of 109 cases treated, 28 were operated upon by the spoon or opening an abscess; 36 were discharged apparently cured; 37 improved; 12 were not cured; 24 patients remain under treatment; of these 14 are already greatly improved. There is, therefore, no doubt of the propriety of employing these parenchymatous injections before resorting to capital operations.—*Wiener Med. Blatter.*

THE action of the salicylates upon the uterus has been studied by Wacker (Cent. f. Gyn. 39), who made the surprising discovery that they possess the power of contracting the uterus and producing metrorrhagic and anti-dysmenorrhœic effects. In two cases of pregnant rheumatics, in the second and fourth months, a dose of forty-five grains *ter die* produced abortion. In six rheumatics during childbed the same dose increased the lochiæ in each case, and reinstated it in one on the twenty-eighth day. In one case the hemorrhage produced by it proved fatal. In five cases in which it was given shortly after the menstrual period, the flow returned. In 33 cases of dysmenorrhœa and suppressed lochiæ, 19 were favorably influenced.

These results are in accord with those of Labadie Lagrave, Britt, Bucquoy, Sabatowsky, and Ballette. The fever cannot be regarded in these cases as the cause of the abortion, because it never exceeded 39.3°, and never reached the temperature of 40–41° C., which, according to Kuminsky, Winckel, and Runge, kills the fœtus. It is probably the hemorrhagic effect of the salicylates, which has been observed in the ear and eyes, which produces the congestion and hemorrhage in the mucous lining of the uterus.

IN the Pediatric Lectra of the Congress of Naturalists, Herr Ranke, of Munich, read a paper on Tracheotomy and Intubation in Diphtheria, with the following conclusions:

1. O'Dwyer's process is in many cases a successful method, and a decided progress.
2. It can never replace tracheotomy entirely.
3. There is no rivalry between them, but one is capable of supplementing the other.
4. The treatment should begin with intubation, and tracheotomy should follow, if it does not succeed.
5. The best results are found in well-appointed institutions.

Ganghofer, of Prague, agreed with Ranke. Bredert prefers tracheotomy. Escherich thinks that while the cases saved by intubation could be saved by tracheotomy, the reverse is not true. Intubation is more easy, technically, and the after-treatment easier, but the conditions of recovery are more difficult. In reality, intubation should be limited to the cases in which the parents refuse permission for tracheotomy, or the latter cannot be properly done for other reasons.

Heubner says that in Leipsig the results were not brilliant, but he thought intubation was more physiological, because it did not involve inhalation of dry air.

Steffen concludes that more observations are necessary to decide the question, but it may be held that hospital physicians ought to treat acute stenosis of larnyx by intubation, this failing, by tracheotomy.

IN the trying cases of atonic post partum h morrhage, any addition to our methods of treatment is welcome. In the Berl. Klin. Wochenschr., of October 14, Dr. Graefe lauds the iodoform gauze tampon highly. It was first recommended by Düehrssen in 1887. The mild cases usually yield to friction, ergot, or hot or cold intrauterine irrigations; for the unyielding cases the tampon is indicated. The uterine cavity is tamponed by three pieces of iodoform gauze, six inches wide and about three and a half feet long; a vaginal tampon will hold the former in position. Patients must be watched carefully, as the tampons may be expelled. The hand upon the uterus should maintain firm contraction whenever it gets soft. Twenty successful cases are reported by several obstetricians.

H. VON HEBRA sums up his paper on the Injection Treatment of Syphilis as follows: The mercurial solutions are to be greatly preferred to the suspensions; they are less dangerous, less irritating locally, and have a better effect upon the system. Their more rapid elimination diminishes the intensity of the possible toxic effects and shortens their duration. They are less painful, and may be more accurately dosed. But they need to be given quite often. If an immediate effect is sought, the most rapidly absorbed fulminate of mercury near the affected spot is indicated; later, the blood-semen mercury, the peptonate and albuminate, and lastly the salt sublimate solution; the latter is most useful as a terminal treatment.

TRACHEOTOMY IN DIPHTHERIA.

So soon as dyspnœa is pronounced, Van Iterson advises tracheotomy, whether it be due to trouble in the pharynx or larynx. This is a new and bold departure. Van Iterson justifies his procedure by claiming that most diphtheritic patients die of transmission of the process to the lungs, by aspiration, which is to be prevented by tracheotomy. Inferior tracheotomy, under narcosis, deserves the prefference; it diminishes the danger from aspiration; fluids do not reach the larynx. After opening the trachea, he cleanses it, as well as the larynx and bronchiæ, by means of a bent sponge probe, and applies iodoform before inserting canula. Out of one hundred such cases fifty-five recovered. In twenty there were no false membranes below the wound; of these fifteen recovered. Four children were saved, although already asphyxiated.

Koch disputes Van Iterson's method, because he had better results without operating so early. In 1887, he had 42.4 per cent. recoveries; in 1888, 38.8 per cent., although the indication and technique after treatment were the same. He operated in one hundred and forty-one cases. Koch, of course, operates in the asphyxiated stage; otherwise he uses, in mild cases of stenosis, inhalations of vapor under a tent, with small doses of apomorphine, spts. ammoniæ anisat. and cassia, which frequently relieves it. But if it fails he endeavors to operate before asphyxia occurs.

Letters to the Editor.

STRONG SOLUTION OF ARGENTIC NITRATE AS AN INJECTION.

A. G., a young man of twenty-five, contracted gonorrhœa in October last. He went to a physician, who put him on the acetate of, and the bromide of, potassium, in three weeks prescribing a mild injection of zinc sulphate. The inflammation at this time evidently extended back to the bladder, for the patient had incontinence of urine. The injection was kept up for some weeks without apparently much good effect. There was never much pain or discharge, and after a time the incontinence ceased. His physician now tried a number of different injections with no result, and the patient finally drifted into my hands. I tried successively mild injections of nitrate of silver solution, bismuth, sulphate of zinc, Mitchell's bougies, and his post-urethral syringe. There still remained a slight oozing of a mildly purulent character. But upon using once a day this preparation,

℞.—Ext. hydrastis fluidi . . . . . f℥j.
Bismuthi subnitr:tis . . . . . ℥j.
Boroglyceridi,
Mucil. acaciæ . . 5 per cent. āā ℥ss.—M.

more or less diluted, the discharge was reduced to a few drops daily of a serous fluid, and there was some pain at each urination. Bougies were now tried, with the result of finding a slight restriction of the urethral caliber about two inches from the meatus, and an exquisitely sensitive prostate, showing a subacute inflammation there. By this time the patient had been under treatment six months—three under the first physician, and the same under me—and as he manifested a disposition to go elsewhere—as the bougies seemed to be doing little good—and as he would not submit to urethrotomy, I decided to resort to a rather strong measure to restore firmness to the relaxed mucous membrane of his urethra.

First, I injected a drachm of a 10 per cent. solution of cocaine, holding it in five minutes. The excess I washed out by an injection of warm water.

I now injected a drachm of a strong solution of nitrate of silver, gr. x to ℥j, allowing it to remain in about two minutes.

The only pain experienced was some burning afterwards, which I stopped with another injection of cocaine. The penis shortly began to swell and to discharge pus quite freely. I put the man to bed and had him keep the parts wet all afternoon with lead water and laudanum, which kept down the pain and swelling. By morning the swelling was nearly gone.

For several days there was pain on urinating, but this was rendered slight by large doses of acetate of potassium.

The point of this account is that from the time of recovering from the effects of the nitrate of silver, the patient has had neither pain in nor discharge from his urethra. ERNEST SANGREE, M.D.

THIOL IN SKIN DISEASES.—In the treatment of eczema, pemphigus, seborrhœa, acne, dermatitis herpetiformis, and possibly other forms of cutaneous disease, the new drug thiol (if present results are borne out by subsequent trial) will be found valuable. While it is found in commerce in both powder and liquid form, the powder is preferable; it is best used with bismuth subnitrate or starch, or, preferably, thus:

Thiol . . . . . ℥j.
Oxide of zinc . . . . . ℥ss.—M.

It is also readily soluble in water, and may thus be applied in all diseases where it is advisable. Its composition is almost identical with that of ichthyol, but it has none of the objectionable features of the latter drug.—*Lanphear's Med. Index.*

TREATMENT OF ENURESIS WITH ANTIPYRIN.—MM. Perret and Dervie, believing that enuresis is due to a spasm of the sphincter of the bladder, treated two cases of nocturnal incontinence of urine with antipyrin in doses of from two to three grammes a day. The trouble ceased ten davs after the beginning of the treatment, and even after the withdrawal of the antipyrin the enuresis did not return.
—*Revue de Thérapeutique.*

ALTHOUGH a large part of the dangers residing in milk are removed by boiling for ten or fifteen minutes, this is but an insufficient safe-guard against tuberculosis; the germs of which resist much longer boiling than this.

Society Notes.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Abstract of Stated Meeting, October 23, 1889.

Vice-President, JOHN B. ROBERTS, M.D., in the Chair.

DR. JOHN B. ROBERTS presented a paper entitled

EXTRACTION OF CATARACT, WITH CASES SHOWING RESULTS OF OPERATION.

He said: In preparing the patient for operation, I cleanse the face in the vicinity of the eyes with soap and water, and subsequently with a solution of boric acid or corrosive sublimate. I then wash out the conjunctival sac with a boric acid solution instilled with an ordinary pipette. The instruments are kept in a similar solution of boric acid, which is made without any great accuracy of strength. A few drops of four per cent. solution hydrochlorate of cocaine is dropped into the eye two or three times during the quarter hour preceding the operation. A few drops of a four-grain solution of atropine is also instilled. Even before the use of cocaine was known, I did not give anæsthetics, because experience has shown me that the operation for the extraction of cataract is not painful, if the surgeon, by previous manipulation of the cornea and lids, teaches the patient to hold perfectly quiet.

The steps of the operation, as I perform it, are as follows: Having grasped the conjunctiva and the inferior rectus with a pair of fixation forceps, I make an upward incision in the cornea with a Graefe, a Beer, or a Jackson knife. I usually prefer the Graefe to the Beer knife.

The iridectomy which I always make, is accomplished by catching and drawing out the iris with an iridectomy hook in the left hand and cutting it with the Levis spring scissors in the right hand. I do not use the iris forceps for making the iridectomy, unless it happen that, for some reason, a portion of the part excised has not been perfectly detached from the iris. I then use the forceps to catch the ragged edges while making a second attempt at complete division.

Laceration of the capsule is done by making a T-shaped incision with a cystotome. Usually I make the horizontal cut of the T across the upper edge of the capsule as a first step, and subsequently make a median vertical slit by another movement. I have, however, on more than one occasion, slit the capsule with a single vertical stroke of the cystotome, The lens is then extruded by pressure upon the sclerotic and cornea, with the finger above and a tortoise-shell scoop below the incision. The finger makes the pressure from the outside of the upper lid. If there is any difficulty, as there often is, in evacuating the soft cortical material or nucleus, I introduce the spoon and extract these remnants. In the event of it being the nucleus which is not properly detached, I often use the wire loop to make traction upon it.

After a few minutes have elapsed to allow reaccumulation of the aqueous humor, I let the patient sit up with his back to the light, and place before the eye which has been operated upon a convex lens of about nine dioptrics, in order that I may prove to him that vision has been restored. By allowing the patient to look about the room and to count my fingers, I give him confidence in the result of the operation; and it greatly encourages him during the stage of convalescence to know that he has actually seen with the eye previously blind.

After instilling a few drops of atropia solution, I seal the eye by means of two or three small strips of ordinary rubber plaster upon the upper lid. These strips of plaster are cut in the shape of a semi-ellipse, and are made to fit the upper lid, but under no circumstances are they to overlap the lower lid. In this manner the upper lid is made stiff and acts as a splint to the wounded cornea. I have never used any other means of dressing after cataract extraction, nor have I ever seen any other method used in the practice of Dr. Levis during the last fifteen or sixteen years.

The advantage of this method is that the eye is not heated, and tears and mucus can drain from between the lids, and atropine solution can be introduced into the conjunctival sac every morning or evening, as the surgeon may deem proper. Before the operation I cut off the eye-lashes of the upper and lower lids, to prevent the eye becoming sealed by dried secretion on the lashes, which gives the patient pain, and has a deleterious effect upon the eye by interfering with the free flow of tears and mucus.

This method of dressing after the extraction of cataract is preferable, I am sure, to the one frequently employed, but which ought to be obsolete, namely, that which covers the eye with a mass of cotton, thus damming up the secretions and causing irritation and congestion.

As a rule, I close only the eye which has been operated upon. I do not restrict the patient to a dark room, nor do I confine him to bed.

Here the doctor reported a number of cases operated upon.

Discussion—DR. GEORGE FRIEBIS: During the past four months I have performed four cataract operations and sent the patients from the hospital. I was encouraged to do this by the fact that one patient, who was sent from the hospital immediately after operation, on account of the presence of erysipelas in the wards, did perfectly well. In the last three cases the vision obtained has been, respectively, $\frac{20}{L}$, $\frac{20}{XL}$, $\frac{20}{L}$.

DR. GEORGE C. HARLAN: There is no doubt that the after-treatment has been much modified of late. The patients are not kept so long in bed, and the dressings are much simpler. A large proportion of careful surgeons still retain the compress bandage, but I know of none who keep it on two weeks. I think it well to use the bandage for two days, and to keep the patient in bed two or three days. We do not now darken the room, but rely on the bandage to keep the sunlight from the eye.

Different antiseptics are used by different operators, but the results are substantially the same. The only ingredient used in common is distilled water, and

that, perhaps, would do as well. As boracic acid has been shown to be without antiseptic qualities, I have abandoned it, and am now using bichloride, 1–5000. Even in this proportion it causes some irritation of the conjunctiva.

There is a strong party in favor of omitting iridectomy in the operation for cataract. For myself I am quite satisfied, not only on theoretical grounds, but from reported results, that the greatest good to the greatest number of cataract patients is promoted by adherence to iridectomy.

I am not sure but that preliminary iridectomy should be performed. I believe that the safest cataract operation is that in which an iridectomy is done not less than one, preferably two or three, months before the extraction. This renders it more easy to avoid inclusion of the iris in the angles of the wound, hemorrhage is avoided, and pain, with the restlessness and muscular spasm which result from it, is absent. Graefe used to advise that preliminary iridectomy should be done when the patient had only one eye, and a distinguished European authority admitted, a few years ago, that in the case of his own father he would do a preliminary iridectomy. There are considerations of expediency opposed to the preliminary operation, but, where it is practicable, I should prefer it.

Dr. B. Alex. Randall: I have thus far done iridectomy in all operations, as it facilitates egress of the lens. A small removal of tissue is generally sufficient; and, after it, I have secured a perfectly mobile pupil, almost as round and perfect for visual purposes as though no iridectomy had been done—the coloboma being thoroughly covered by the upper lid. The corneal section and the exit of the lens are also facilitated by the dilatation of the pupil, which is afforded by the cocaine more thoroughly than by atropine, while cocaine does not interfere with the subsequent action of eserine in contracting the pupil and preventing incarceration of the iris in the wound. I wish to emphasize the point that cocaine must be used with caution, since it affects the nutrition of the corneal epithelium; and our studies show that it is largely upon this epithelium that the healing process depends. It has been pointed out that sometimes, where bichloride of mercury has been used after cocaine, there will be opacity of the epithelium of the cornea, or even its exfoliation. As a wash, distilled water does not seem a good agent for use in these cases, since its specific gravity is too low to make it unirritating. A solution of salt or of boric acid would seem to be best. I am far from believing that boric acid has not powers of value in practical use.

Dr. Roberts: While I am convinced of the value of antisepsis and asepsis, I still am of the opinion that in eye-surgery neither antisepsis nor anæsthesia is absolutely called for. I use them; but I do not think that I have gained so much from antiseptic measures in cataract extraction as in operations in general surgery. In seventeen years' experience in the practice of Dr. Levis and myself, I have not seen, I think, more than one case of sloughing cornea after extraction. Anæsthesia I believe to be necessary only under the most unusual instances.

Dr. Mordecai Price next read a paper upon

ECTOPIC GESTATION.

These cases are far more numerous than you would suppose; in our city alone, from all sources, about twenty-five a year; and when you remember that, five years ago, the mortality was one hundred per cent., and now at least ninety per cent. is saved, we have much to be thankful for to Mr. Tait and his adviser, Mr. Hallwright.

The symptoms of ectopic gestation before rupture are of a vague and uncertain character. Those best qualified to properly interpret them, whose experience in such conditions has been greater than any other investigators, have yet to see one and recognize it before rupture. The only reported cases said to have been recognized and treated before rupture have been in the hands of our electrical friends and enthusiastically dwelt upon, and the man who would treat them with a knife given a back seat and denounced in unmeasured terms for his mutilation of the poor woman when it was so easy to get rid of the product of conception by so easy and safe a plan as the electrical current. But we find by investigation that in many of these reported cases there was little foundation for the belief that they were pregnant. Some of them have fallen into the hands of other men and been operated on, and no pregnancy existed. And I cannot but think the others could not bear investigation requisite to a proper diagnosis.

The symptoms after rupture are sufficiently plain and urgent. In a woman who has been sterile for a length of time, it may be for years, whose period has been delayed for two or three weeks or longer, after slight exertion or lifting some heavy object, there occur agonizing pelvic pain and collapse, followed by all the symptoms of loss of blood. If the patient reacts, this is followed by recurring pain and collapse, constant uterine hemorrhage, it may be with small loss of blood, discharges loaded with shreds of decidua, leaving the impression in the patient's mind that she has had a miscarriage. There is pain and fulness on the side of rupture, with a mass of a baggy, fluctuating consistency in the pelvis. No one case being a repetition of any other, there is nothing fixed and unchangeable save the termination of the disease—death, almost without exception, unless prompt surgical aid is given.

There are many conditions that may be confounded with extra-uterine pregnancy. In fact, any mass in the pelvis, such as tubal trouble, a small ovarian or dermoid tumor, hæmatocele from traumatism, an abscess of the tube or ovary, gonorrhœal pyosalpinx, all have been mistaken for extra-uterine pregnancy.

Even our electrical friends have mistaken tubal trouble for extra-uterine pregnancy, and wasted many valuable sittings to kill the fœtus where none existed, and, strange to say, they did not cure the diseased tube.

But these mistakes of diagnosis are of small moment, as the conditions which could be mistaken for extra-uterine pregnancy should all be removed by the knife. I have seen the abdomen opened several times when a positive diagnosis had been made, where no

pregnancy existed, and a small pus tube or dermoid tumor instead. I am sure the operator was not greatly disconcerted by the conditions found.

We have come to that period where the experimental treatment of ectopic gestation is a disgrace to our profession. Electricity, with all its barbarous instruments and murderous delays will, I hope, ere long, be forever thrown aside as a means of treatment for this condition. Its history certainly does not offer to any thinking mind any proof of its value, while on the contrary its record of death is truly appalling. Puncture, or injections into the sac of morphine, or any substance, with the hope of killing the fœtus, is attended with greater risk to the mother than an immediate operation for its removal. I can find no language strong enough to express my condemnation of these experimental methods.

Operation —Where there is time, the room should be thoroughly cleaned, and all needless articles of furniture removed. A most efficient cleansing of the body with soap and water and brush is necessary, and the bowels should be thoroughly evacuated. No antiseptic should be used. If possible, a trained nurse should be obtained; one who is accustomed to the work of the operator, able to cleanse and take care of a drainage tube and encourage the patient to bear patiently with the discomforts necessarily following an operation of this kind. Opium must be positively forbidden in all abdominal work—it interferes with the secretions, sickens the patient, makes her irritable and hard to manage, and conceals the symptoms of danger, and otherwise complicates the recovery.

A good light is needed. Every instrument and ligature and suture should be carefully scalded and placed in trays of warm water, handy to the operator or his assistant, so that in case of any emergency there will be no delay; for time is a material factor in these operations. The shorter the operation the less the shock. It should be minimized in every detail; short incision, careful enucleation, perfect tying, most thorough irrigation with warm, distilled water. No antiseptic whatever has any place or purpose in this operation. Antiseptics have done bad work for good operators. We see this admission in the journals almost daily—"perhaps the antiseptic was too strong." Chemical antiseptics of any kind in the peritoneum do murderous work, and should be abolished by law, if our surgeons have not sense enough to discard them in this department of surgery. The after-treatment in these cases is of great importance. The drainage-tube should be cleansed every half hour for the first day or two, until the discharge becomes small in quantity and serous in character, when it should be removed. The contents of the bowel should be kept in a soluble condition; and it should be purged with Epsom salts upon the slightest indication of peritonitis, when the symptoms will disappear like magic. The patient should be kept in bed from three to four weeks in the most favorable cases, and longer if deemed advisable.

Discussion.—Dr. A. J. Downes: While in Atlantic City a year ago, I was hastily called to see a woman in collapse. There was great abdominal pain. She had had two attacks of pain and collapse on the day before I saw her. At 10 A. M. she had an attack, and at 11 o'clock I saw her. In the afternoon she had a fourth attack and died. The point I wish to raise is whether, after the third collapse, with the abdomen filled with blood, a surgeon could go in without trained assistants, with a prospect of relieving the patient?

Dr. J. Hoffman: It is unfortunate that some of the advocates of early diagnosis are not present. A case has recently been reported where it was claimed that a five months' fœtus was melted away. Such a thing as that is impossible. Such reports cast disrepute upon electricity. Probably no series of cases has attracted so much attention as that reported by Dr. Thomas. I have carefully gone over them, and so far as they relate to the question of early diagnosis they are of no value.

I have myself twice operated, expecting to find extra-uterine pregnancy, but failed to find it. Once, when operating for something else, I did find it.

The treatment by puncture seems to me to be bad in all cases. Apostoli recommended puncture two years ago, but he had not tried it himself. The records of abdominal surgeons are positive; they know what they find and what they accomplish, and are entirely opposed to the theoretical part of the question, such as electricity must always remain.

Dr. J. Price: In a case recently operated on, where there was a fairly good history of ectopic gestation, I removed from one side an ovarian blood-cyst. Blood-cysts have often been considered ovarian pregnancies. If these are ovarian pregnancies, they are exceedingly common. More than one-half of the cases of ectopic gestation die suddenly, before there is any suspicion of pregnancy.

In regard to the removal of the other tube and ovary in these cases. In one instance Mr. Tait removed an ectopic gestation and saved his patient. Two years later she conceived on the other side, but let the matter go without consulting a physician; the sac ruptured and she died. Dr. Sutton, of Pittsburgh, had a similar experience. In removing an ectopic gestation, I have thrice found on the other side a small ovarian cyst, hydrosalpinx or a pus tube. It is now a rule with me, if the patient's strength is fairly good, to remove the other tube.

Dr. M. Price: In regard to the medico-legal aspect of this question. Some years ago a case occurred in which the woman died of internal hemorrhage. The physician making the autopsy did not say positively that the hemorrhage was caused by instrumental bad management of the case, and the doctor was convicted. My impression is that the woman had extra-uterine pregnancy, and that the manipulation of the uterus had caused rupture. If a case of extra-uterine pregnancy were roughly examined, rupture might very readily be produced. In such a case the surgeon would be justified in opening the abdomen with a penknife and securing the vessel. The first thing to be done is to get hold of the pedicle and put on a ligature. This is the only way to stop the hemorrhage.

Cincinnati Letter.

AN effort is being made to start another Woman's Medical College in Cincinnati. Cincinnati has too many teaching institutions in medicine now, and when will she stop? Professors are thick and growing thicker. One of our plain doctors went out the other day to take a walk to reduce his corpulence, and happened, after walking most of the afternoon, to meet another plain doctor out walking to get an appetite so he could eat more and grow fat. Says Doctor D. to Dr. K., "Say, doctor, I don't see your name on any college catalogue; let's start a college and be professors." "Oh, no," replied Dr. K., "let's don't, it's too common.

Papilloma of the bladder in the female is treated very successfully in the Cincinnati Hospital by Dr. C. D. Palmer, by washing out the bladder every other day with a saturated solution of boracic acid in water, and giving internally the following prescription:

R.—Acidi borici . . . . . ℥j.
Tr. hyosciami . . . . . ℥ss.
Infr. buchu . . . . . ℥iss.
M.—S. One teaspoonful every three hours.

In cases where this does not suffice the doctor scrapes out the papilloma with a sharp curette, though this is seldom necessary, if the case is seen early.

The Cincinnati Obstetrical Society held its October meeting at the residence of Dr. E. S. McKee. The paper of the evening was read by Dr. E. W. Mitchell, on Dysmenorrhœa.

The annual election of officers at the Cincinnati Medical Society resulted as follows: President, Dr. C. R. Holmes; Vice-president, Dr. Wm. L. Mussey; Secretary, Dr. E. S. Stevens; Treasurer, Dr. J. C. Oliver; Corresponding Secretary, Dr. A. D. Birchard. An interesting report of a case of popliteal aneurism was made by Dr. W. L. Mussey, one of infectious phlegmon of the larynx by the retiring president, Dr. Joseph Eichberg and a case of cockle bur in the larynx by Dr. J. A. Thompson. The retiring president has, during his term of office, merited the respect and good will of all who have come under his rulings.

Clinical Significance of the Tendon Reflexes was the subject of a paper read before the Cincinnati Medical Society by Dr. Philip Zenner, from which the following is an abstract:

"Reflexes which are present in healthy individuals may be absent or may be in pathological excess; hence the significance of tendon reflexes in disease is dependent on the fact that they may be in a different condition from their state in normal subjects."

The author dwelt on certain phenomena in his paper. First, the absence of the patellar tendon reflex or knee jerk. As this is almost invariably found in healthy individuals, its absence is a very significant symptom. Second, the presence of ankle clonus or exaggerated Achilles tendon reflex. As this is rarely found in health, its presence is also significant.

The patellar tendon reflex is absent whenever there is disease in any part of its reflex arc, that is, the quadriceps femoris muscle, the crural nerve and its anterior and posterior roots, and the posterior column and anterior gray matter in the lumbar region of the cord. It is absent when there is neuritis of the anterior crural nerve, and this is the cause of its absence in some cases of diphtheritic and alcoholic paralysis, diabetes mellitus, paralysis from arsenic and other metallic poisons. It is often absent in anterior poliomyelitis, especially the infantile spinal paralysis, and is a reliable sign in these cases because it is present at a very early period. This sign is of most service in helping to diagnose or exclude locomotor ataxia. It is most valuable because it is always present, and at a very early period, in this disease.

The author then reported a number of cases which appeared to be very obscure, in which the presence of the knee jerk enabled him to exclude or its absence to diagnose locomotor ataxia. He also reported cases of general paralysis of the insane in which this symptom aided his diagnosis, for absence of patellar tendon reflexes and spinal myosis are very frequently found in this form of insanity.

The knee jerk is often difficult to elicit, even in healthy subjects; it should, therefore, never be declared absent without very careful examination, especially after Jendrassik's method. The patient is seated on a table so that the legs hang freely, the knees are laid bare; then the patient is told to clinch his hands and pull them forcibly apart; while his muscles are thus in a state of tension, the examiner strikes upon the ligamentum patellæ in every part. This method very much intensifies the knee jerk.

The patellar tendon reflex is often very slight in healthy persons, so that a slight response has no clinical significance; but when it is observed to gradually become less, week by week, or to be much less on one side than on the other, it arouses a suspicion of disease of the cord.

The ankle clonus is usually found when there is disease of the antero-lateral tracts of the cord, in various forms of myelitis, and in secondary degeneration of the pyramidal tracts after disease of the brain.

It often enables us to distinguish between hysterical and organic disease of the cord when otherwise a diagnosis is difficult.

This symptom is also of much value in prognosis in determining whether a hemiplegia following a cerebral lesion will be permanent. The earlier the ankle clonus can be elicited after the occurrence of the paralysis, the more unfavorable the prognosis.

CURE OF A CASE OF EXOPHTHALMIC GOITRE.—M. Gérin Rose reports a cure in a case of exophthalmic goitre existing in a woman thirty-six years of age. The case was complicated from the start, with marked gastric disturbances. The ordinary treatment was without result, and the symptoms did not pass away until after a sojourn in the country. This recovery has been kept up for eight years.

—*Revue de Laryngologie.*

Book Reviews.

CLINICAL LECTURES ON MENTAL DISEASES. By T. S. Clouston, M.D., Edin., F.R.C.P.E., Physician Superintendent of the Royal Edinburgh Asylum for the Insane; Lecturer on Mental Diseases in Edinburgh University, etc. To which is added an abstract of the Statutes of the United States and of the several States and Territories Relating to the Custody of the Insane, by Charles F. Folsom, M.D., Assistant Professor of Mental Diseases, Harvard Medical School, etc. Octavo volume of 541 pp., with eight lithographic plates, four of which are colored. Cloth, $4.00. Henry C. Lea's Son & Co., Philadelphia.

In marked contrast to the abundant literature upon mental diseases is the slight attention usually paid to the study of these affections in the average medical school. No one can deny but that a knowledge of the workings of the mind, both in health and in disease, is a prime requisite of a complete medical education. However materialistic as physicians our views may be, we are compelled to recognize the existence of certain forces that are intangible and so far unlocalized, making up the complete picture of vitality. These forces, whether we name them spirit, mind, or what-not, are existent, and their intimate relationship with physical diseases of all sorts demands of us their closest study. Not only as alienists but as general practitioners we should be as familiar with them as possible. The moods of an individual are undoubtedly often dependent upon his digestion, and one would be rash indeed to say that such was always the case, as instances are frequent enough where the mood is the power affecting the digestion. And so on from such slight mental aberrations all the way up to the most hopeless forms of insanity the mind and its manifestations need to be understood, both in itself and in connection with organic lesions.

The study of psychology requires the strongest powers of the intellect, coupled with the most determined concentration, and it is this, perhaps, added to the lack of time, that has rendered the study such a neglected one in the college curriculum. Both as students and practitioners we are loath to burden ourselves with what is abstruse; we prefer to turn to that which is more gross, more impressive in its results before the laity, and so more immediately profitable to our own interests. But all this is a mistake, for there is scarcely a physician—particularly those away from the great centers of specialism—who may not, at one time or another in his career, be called upon to decide the mental condition of individuals; then, unless he be fully prepared and guarded in his opinion, misery will be his lot, or possibly a damaging lawsuit.

These well-known clinical lectures of Dr. Coulston are the best that we know of for the general practitioner. Without loading his book with abstruse problems and metaphysical theories, the author has arranged the whole class of mental diseases in such a way that they may be readily comprehended and easily studied. His classification, though not entirely satisfactory, is yet one of the most complete and practical known to this department of medicine. The special feature of the work, however, is the large number of cases reported from the author's own experience. This, as anyone can understand, is of unusual value in rendering the book practical and fit for the readiest reference. The work has long been one of the highest authorities among the English physicians, and the American edition, published under the supervision of Dr. Folsom, is further enhanced by the addition of an appendix relating to the statutes of this country for the care of the insane. The work of the publishers has been done in a manner worthy of so useful a contribution to the literature of mental diseases, and we therefore take pleasure in commending this book as a standard both for specialist and general practitioner.—L. H. M.

Pamphlets.

Clinical Observations on Some of the Effects of Direct and Indirect Traumatisms of the Brain. By R. Harvey Reed, M.D., Mansfield, Ohio. Reprint from Times and Register, August 24, 1889.

The Influence of Sewage and Water Pollution on the Prevalence and Severity of Diphtheria. By C. W. Earle, M.D., Chicago. Reprint from Archives of Pediatrics, November, 1888.

Infant Feeding. By Chas. W. Earle, M.D. Reprint from Journal of the American Medical Association, August 4, 1888.

Antiseptic Obstetrics. By Chas. W. Earle, M.D., Chicago. Reprint from Transactions of the Thirty-seventh Annual Meeting, Illinois State Medical Society, held in Rock Island, May 17, 1888.

Thirty-fourth Annual Announcement of the Kentucky School of Medicine, Louisville, Session of 1890. Courier-Journal Job Printing Co.

Influence of Music and its Therapeutic Value. By Sebastian J. Wimmer, A.M., M.D., St. Mary's, Pa. Reprint from New York Medical Journal, September 7, 1889.

The Medical Digest.

A PHYSICIAN of Roumania was severely bitten by a hydrophobic soldier, and has placed himself under treatment in the bacteriological institute at Bucharest.

ERGOT IN LABOR is advised by Schatz in the form only of fresh fluid extract, whenever the pains are feeble. It produces normal pains, which are not increased in intensity, but in number. Ten to twelve drops hourly regulate the pains, and should be used more frequently than is now the custom. The pains should be corrected by a guide.—*D. Med. Zeitung.*

CHRONIC COLD ABSCESSES OF THE GLANDS are treated by Lassere by injection of:

℞.—Naphthol-β 5.0
Alcohol (90°) . . . . . 33.
Aq. dest. q. s. ad 100 C.C.
Filter.

This is placed in hot water while being used; the syringe should also be warmed. The abscess is filled with the fluid.—*Ber. Klin. Wochenschrift.*

MIGRAINE is treated by E. Goubert with small doses of bromide of gold, 3 mg. in a glass of water an hour before breakfast and supper. In a few days the attack remains away, or becomes less frequent, Treatment for six or eight weeks generally prevents the attack for a long time, sometimes entirely. The paroxysm may also be rapidly checked by a dose of three mgr. in its inception; to be repeated in an hour if necessary.—*Wiener Med. Presse.*

PERNICIOUS VOMITING OF PREGNANCY.—A case reported in the *Wiener Med. Wochenschrift* deserves attention. All remedies having failed and abortion being declined, recourse was had to enemata of $\frac{1}{5}$ litre milk at 35° C., with 2.0 chloral and pot. bromide and the yolk of one egg. After several days constipation, $\frac{1}{5}$ litre of milk with 8.0 salt, and repeated in half an hour, produced an abundant stool. Afterwards the patient retained milk and broth, and slept well. After a few relapses, which were similarly treated, she recovered completely.

ELECTRICITY IN GYNÆCOLOGY ACCORDING TO APOSTOLI'S METHOD.—The author has treated during the last academic year thirty patients. The diagnoses (confirmed in consultation, among others by Prof. Sneguireff) were twelve cases of salpingitis, four of oophoritis, six of metritis, three of amenorrhœa, five of fibromata, and one of atrophic parametritis.

The following conclusions were drawn:

1. In salpingitis (hydro- or hemato-) the continuous current (180–250 milliamperes) gave most brilliant results. In pyosalpingitis the results amounted to nothing (two cases), thus affording perhaps a means of differential diagnosis. There was the same elevation of temperature, up to 38° and 38.5° Cent., in both cases, and the electricity had to be abandoned after five sittings.

2. In three cases of chronic inflammation of the ovaries, the size of the ovary returned to normal and the pains disappeared (160–220 milliamp.)

3. In chronic metritis the author preferred electricity to massage, for he has seen the uterus invariably diminish in size almost to half, after seven seances, and the pains disappear (save in one case, in which the patient could not bear more than 80 milliamp.) with currents reaching the height of 280 milliamp.

4. In amenorrhœa the author had had one success; in two other cases, one patient could not bear more than 50 milliamp., and the other received the application of electricity only four times in four months.

5. In fibromata he believes that it is an unpardonable error to operate without first testing electricity, whatever may be the size of the tumor.

6. In a case of atrophic parametritis (cirrhotic) the cure was not complete, although the painful symptoms had disappeared and the exudation had diminished by half.—*Gazette de Gynæcologie.*

STILL another candidate in the hypnotic way appears in *somnal*, a chemical compound of chloral, urethane, and alcohol, which is being introduced in Germany. It is said to be free from the uncertainty of chloral, producing sound sleep in about half an hour after administration, and without after ill effects. One would think that the uninterrupted deluge of soporifics to which we have been treated lately would have driven morphine out of medical practice entirely. It holds its own bravely, however, and is likely to survive the demise of many of its modern rivals.—Canada *Pharmaceutical Journal.*

MEDICAL MISCONCEPTIONS ABOUT LITHIUM SALTS.—It is commonly believed that the salts of lithium possess special power in preventing the deposition of uric acid in the tissues, or for dissolving and removing deposits which have already formed. As a result these salts have been largely employed in medicine, but from a paper read by Prof. L. Siebold, at the British Pharmaceutical Conference, it appears that there is no ground for believing that the salts of lithium possess any advantage over the corresponding compounds of allied metals.

Prof. Siebold's conclusions are as follows:

1. The relative solvent action of solutions of lithium, sodium, and potassium carbonates on a given weight of uric acid, under equal conditions of dilution and temperature, is strictly proportional to the ratio of the molecular weights of these solvents. (The determinations were made at 37° C., and the proportion of water to uric acid was not much greater than that occurring in urine.)

2. Equivalent proportions of the three solvents named dissolve equal quantities of uric acid under equal conditions of dilution and temperature. (Experiments conducted on the same lines as in 1.)

3. Crystals of uric acid deposited from urine show the same behavior towards the solvents named as the pure uric acid used in 1 and 2.

4. Equal weights of a urinary sediment consisting of acid urates, are dissolved by quantities of the three solvents named, proportionally to their molecular weights.

5. Lithium chloride and lithium sulphate exercise no solvent action on uric acid and acid urates.

6. Natural mineral waters containing lithium have no solvent action on uric acid beyond that exercised by basic constituents simultaneously present, and by the water.

7. The degree of alkalinity produced by the internal administration of medicinal doses of lithium citrate is not greater than that produced by equivalent doses of potassium citrate. It is greater than that produced by equal doses of the corresponding potassium salts, but only so in proportion to the molecular weights. (All these experiments were conducted under strictly equal conditions of diet. The alkalinity was determined in the urine of twenty-four hours.)

Lithium salts are known to be more toxic than potassium salts, and hence less suitable for prolonged administration. Altogether, the superiority of lithium salts as remedies in calculus, gout, etc., appears much overrated.

DR. ALFRED L. LOOMIS says he is strongly opposed to smoking in the morning. Smoking moderately at any time after luncheon, even just before retiring, he does not consider injurious.

DR. QUINDORA MCQUAID, assistant resident physician in the women's department at the State Hospital for the Insane, and Dr. J. G. Bauman, of Telford, have been elected members of the Montgomery County Medical Society.

THE New Home for Convalescents, at 35 North Fortieth Street, is almost completed and will be opened in a short time. The home is a three-story brick building with a stone front, forty feet long by seventy feet deep.—*Press.*

MRS. CAROLINE A. WENTS, of this city, has, through her friend, Mrs. George E. Stubbs, given $5,000 to endow a perpetual free bed in the Medico-Chirurgical Hospital, to be known as the Ann Emerick bed, in memory of her deceased mother.

LAST week Philadelphia recorded sixteen deaths from typhoid fever, nine from scarlatina, sixty from consumption of the lungs, twelve from croup, ten from diphtheria, and thirty-five from pneumonia; total from all causes three hundred and ninety-nine.

THE Philadelphia Board of Health has of late shown an unwonted degree of activity. One of the projects recently broached is the construction of a crematory for the destruction of bodies of paupers and others who die of small-pox and other contagious diseases, which render them unfit for dissection.

DIPHTHERIA broke out in the Children's Home and the County Almshouse, Washington, Pa., Nov. 9. Ten deaths have occurred in the former institution and five are now ill with the disease.

IN the Florida Everglades, a man had his leg crushed by the fall of a tree. As there was no physician within reach he let nature take its course, and the leg rotted off at the knee, the man recovering without any symptoms of gangrene.

From July 27 to September 26 there were 6,173 deaths from cholera in Mesopotamia reported; but this is below the truth, as many cases are not reported. The epidemic has subsided in that province, but has spread to an alarming degree in Persia.

GOV. FORAKER'S private secretary announces that the Republican candidate has "peritonitis of the stomach." It is further said that Foraker gained 5,000 votes by this affliction. If he had been attacked by spinal meningitis of the heart or albuminuria of the lungs he might have been elected.

IT is reported in the usually correct and trustworthy *Record* that Professor S. G. Dixon has succeeded in attenuating the tubercle bacillus until he has obtained a variety which, itself harmless, still protects rabbits against inoculations with the virulent, unattenuated bacillus.

Some of the Indiana school teachers are in favor of a course of instruction on the effects of tight lacing and injurious cosmetics, and resolve to denounce these evils, as well as those of gum-chewing, and the use of wire, cotton, saw-dust, etc., to improve the contour of the human form.

THE Board of Health has made additions to the laws governing interments in cases of contagious diseases. The *Inquirer* comments thereon: "If the citizens will not observe sanitary precautions while alive, the Board is bound they shall have the full benefit of them after death."

THE Spanish bark Canaria came into one of our ports with yellow fever on board. It was found that she had taken on ballast at Havana, from a pile of stone over which the sewe s of Moro Castle pour the dejecta from Spanish soldiers sick with yellow fever. Will the world *ever* learn anything?

THE first of a series of scientific lectures, under the auspices of the Odontological Society of Pennsylvania, was given in Justi's Hall, northwest corner Thirteenth and Arch streets, on Saturday evening, November 2, 1889, by Ernest Laplace, A.M., M.D. (Paris), Professor of Pathology in the Medico-Chirurgical College, Philadelphia, the subject being "Fermentation, Its Cause and Effects."

DR. JOHN T. GREEN, Chief Resident Surgeon of the Presbyterian Hospital, has resigned, in order to travel as physician to a private family through the West during the winter. By Dr. Green's resignation Dr. S. D. Van Meter becomes Chief Resident Surgeon, Dr. Benjamin McGuilliard, Junior Surgeon, and Dr. William C. Posey, Senior Physician.

The seventy-first annual report of the Northern Dispensary, No. 608 Fairmount avenue, just issued, shows that during the past year 14,242 patients were treated there, and 27,988 prescriptions filled free of charge. This work was accomplished at a cost of $5,023.42, an average cost of eighteen cents for each patient treated.

THERE is renewed trouble in the Woman's Homœopathic Hospital of Philadelphia. Last year the staff resigned, because they were not allowed to use other than strictly homœopathic remedies in strictly homœopathic doses. Now, it appears that the hospital is suffering from an acute attack of Christian science; and as an indirect but effectual remedy the pure Hahnemannians have had the leading faith curist arrested for practising without being registered. Let the good work go on.

PROF. S. B. HOWELL has resigned his chair in the faculty of the University of Pennsylvania, in order to devote his whole time to his classes in the Medico-Chirurgical and Philadelphia Dental Colleges. The Board passed a vote of thanks to Professor Howell for his many years of excellent service. Edward D. Cope was elected to succeed him. Professor Cope is one of America's foremost geologists, and will probably soon qualify himself for the teaching of mineralogy.

THE American Institute Fair will positively close on Saturday evening, November 30. There is not much time till then, and there is so much worth seeing that neither old New Yorkers nor young New Yorkers, nor the friends and visitors of both can afford to lose the opportunity afforded of visiting the exhibition. The best people of the city go to the fair. It is conveniently reached, being at Third avenue and Sixty-third street, and there is much more than twenty-five cents worth of amusement and instruction to be had for the price of admission.

WHEN may refugees safely return to their homes after yellow fever?

This question is answered as follows by Joseph Y. Porter, State Health Officer of Florida:

After the occurrence of ice;

After the occurrence of three killing frosts;

After the occurrence of no cases of fever for a period of two weeks; and

After thorough disinfection and ventilation of all localities infected and bedding and such other articles as are capable of conveying germs.

THE report of the West Philadelphia Hospital for Women, at Forty-first and Ogden streets, for October, gives the following statistics of work done during the month: Patients treated in dispensary, 65: in the hospital, 4; in the out-practice, 8; number of visits to the dispensary, 129; to out-patients, 51, and number of prescriptions compounded, 131. The hospital is still in need of money, not being able to do as much as would be desirable for those applying for aid, on account of the lack of money and appliances.

At the session of the American Public Health Association in Brooklyn, Dr. Lee, of Philadelphia, offered resolutions asking the Government to purchase the island of Cuba, as a sanitary measure of precaution against the spread of yellow fever, small-pox and leprosy. Dr. Lee considers the insufficiency of precautionary measures in Cuba a constant menace to the people of the United States. If our people could be brought to realize the enormous cost of an epidemic they would understand that the cost of such an investment as Dr. Lee suggested would be amply repaid by the results in the prevention of disease alone. At present Cuba is a standing menace to our Southern States.

To Contributors and Correspondents.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the co lumns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

ACCORDING to the rates of mortality in thirty-eight large cities in the world, San Francisco ranks as the first, and Philadelphia the second, in healthfulness.

Army, Navy & Marine Hospital Service.

Changes in the Medical Corps of the United States Navy for the week ending November 9, 1889.

Surgeon B. F. Mackie and Assistant-Surgeon Geo. McC. Pickrell, detached from the U. S. S. Ossipee, and placed on waiting orders.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service for the two weeks ended November 9, 1889.

PURVIANCE, GEORGE, Surgeon. Granted leave of absence twenty-one days. November 8, 1889.

AUSTIN, H. W., Surgeon. To inspect unserviceable property at St Louis Marine Hospital. November 4, 1889.

GASSAWAY, J. M., Assistant-Surgeon. Relieved from duty at New Orleans, La., to rejoin station at Cairo, Ill. October 23, 1889.

BANKS, C. E., Passed Assistant-Surgeon. Granted leave of absence for thirty days. October 28, 1889.

STONER. J. B., Assistant-Surgeon. Ordered to Vineyard Haven, Mass., for temporary duty. November 6, 1889.

CONDICT, A. W., Assistant-Surgeon. Ordered to Cairo, Ill., for temporary duty. Nov. 4, 1889.

GUITERAS, G. M., Assistant-Surgeon. Ordered to Washington, D. C., for temporary duty. November 8, 1889.

GROENEVELT, J. F., Assistant-Surgeon. Ordered to New York, N. Y., for temporary duty. November 5, 1889.

Medical Index.

We purpose on this page to give a list each week of the more important and practical articles appearing in the contemporary foreign and domestic medical journals.

Arthropathies, traitement (suite), par M. le Prof. Guyon, Annales d'Orthopédie, Oct. 15, 1889.

Apparent cancerous transformation of syphiloma of the tongue, excision by the galvano-cautery, G. Frank Lydston, M.D. Chicago. N. Y. Med. Record, Oct. 26, 1889.

Actinomycosis, Danforth. The Med. Current, Sept., 1889.

Brain specimens chiefly illustrating localization, Chas. K. Mills, M D. University Medical Magazine, Nov., 1889.

Case of papillomatous urethritis, F. M. Briggs, M.D. Boston Med. and Surg. Journal, Oct. 24, 1889.

Clinical observations on rhus toxicodendron, John Aulde, M.D. Therap. Gaz., Oct. 15, 1889.

Cholecystotomy by lumbar incision for distended gall bladder simulating floating kidney, J. Ewing Mears, M.D. Annals of Surgery, Oct., 1889.

Convenient and comfortable dressing for fracture of the bones of the hand, Geo. F. Beasley, M.D. Amer. Practitioner and News, Oct. 26, 1889.

Discussion on an estimate of the value of electricity in gynecology. Brit. Med Journal, Oct. 19, 1889.

Discussion on the treatment of retention of urine from prostatic enlargement. British Medical Journal, Oct. 19, 1889.

Des deformations permanentes des doigts déterminées par la tuberculose de ces organes. par M. le Prof. Lannelongue (Paris). Annales d'Orthopédie, Oct. 15, 1889.

Des greffes appliquées à la guérison des difformités par des cicatrices, par M. Heidenreich (de Nancy). *Ibid.*

De l'absinthe; étude physiologique de la liqueur d'absinthe et des essences qui entrent dans sa composition, J. V. Laborde, rapporteur. La Tribune Méd., Oct. 10, 1889.

Des tractions soutenues, par M. Chassaguy (de Lyon). Revue Médicale, Aout, 1889.

Dyspepsia and its treatment, Edwin Carson, M.D., San Diego, Cal. Southern California Practitioner, Oct., 1889.

Clinical Lecture.

Delivered in the Bellevue Hospital, October 8, 1889.

BY FREDERIC S. DENNIS, M.D.,

Professor of Principles and Practice of Surgery, Bellevue Hospital Medical College.

Reported by DR. K. B. PAGE.

GENTLEMEN:—The first case that I shall present to you this morning is that of a pistol shot wound of the thigh. This patient was shot one week ago, by a revolver carrying a 32 calibre ball. He was admitted to one of our city hospitals, and he was subsequently transferred to Bellevue.

Upon examination of the thigh, there is found a wound of entrance upon the outer and upper aspect of the limb, but no aperture of exit of the bullet. You must study carefully the difference between the wound of entrance and that of exit, as often a most important medico-legal point arises in connection with this subject. The aperture of entrance is circular, owing to the shape of the missile; its circumference is smaller than that of the bullet, owing to the elasticity and contractility of the skin; its edges are inverted and surrounded by an areola of ecchymosis. The exception must be remembered, that if the bullet is fired very near the body, the aperture of entrance may be larger than that of exit, and powder stains may be visible.

The aperture of exit is ragged and contused; its circumference is larger than that of entrance, but not larger than the bullet; its edges are everted and lacerated. Another exception is to be remembered in this connection, and that is if splinters of bone or foreign bodies have been driven through in advance of the bullet, the aperture of exit then resembles a tear, and the wound is irregular. If suppuration has been established, the entrance and exit wounds are both changed on account of the superficial sloughing.

In the present case the condition of the wound is what might be expected by repeated examinations. This fact leads me to the important consideration of the management of pistol-shot wounds. I have collected a large number of cases of gun-shot wounds occurring in my hospital practice, and the results of treatment point clearly to the conclusion that absence of probing, immediate antiseptic irrigation of the wound, hermetically sealing by styptic collodion, application of antiseptic dressings and fixation by splints embrace the routine plan of procedure.

Probing is useless and dangerous. The information derived from the use of the probe is uncertain and unreliable. The bullet track is filled with blood. Probing disintegrates the coagulum, which is nature's method of obliterating the newly-formed track, and allows air to enter the wound, and in many cases the probe is the starting-point for septic infection of the wound. If this view be correct in regard to the ordinary pistol shot wounds of the soft parts belonging to the extremity, it is of the greatest importance not to probe wounds involving the great cavities of the body. But a full discussion of this subject will be entered upon in the course of didactic lectures upon gunshot wounds.

To return to the patient: In examining the soft tissues above the joint, I feel a small, hard body, which I take to be the bullet, and I have asked Mr. Ford to send to the clinic this morning one of Dr. Girdner's telephonic bullet probes. I will now take

this needle, and after carefully cleansing it, and under continuous antiseptic irrigation, will thrust it into the soft tissues upon the foreign body. If the needle impinges upon the lead bullet, at once the telephone bell will ring, our diagnosis will be scientifically confirmed, and an operation indicated with a view to extracting the bullet. The Girdner telephonic bullet-probe is, without doubt, a surgical instrument of great value. I believe, however, its use is mainly restricted to a confirmation of diagnosis. As a means of finding a bullet without any knowledge of its situation, it is likely to become a source of danger. For example, it should not be thrust indiscriminately into the peritoneal, pleural or cerebral cavities. It may be employed about the extremities in the manner I shall demonstrate this morning.

The expert assures me by the ringing of the bell that I am now on the bullet, and with my scalpel I shall cut down upon the foreign body; and now, gentlemen, you see the bullet, which I have just extracted with the forceps. Thus you see that this demonstration corroborates what I have already said in regard to the use of this instrument. The wound will be dressed antiseptically, and in a few days the parts will be healed by primary intention.

In dismissing this case, gentlemen, remember that a bullet usually does injury in its passage through the body, and that its lodgment is attended with no harm. I recently detected with this probe a bullet that had been in the thigh nearly thirty years, and it never gave rise to trouble until a few weeks ago, when the patient injured his thigh by falling. You can wait for many days before extracting a bullet, and when the parts have returned to their normal condition, the bullet can be extracted under antiseptic precautions with absolute safety.

FEMORAL HERNIA.

The next case is one of femoral hernia, and I propose to cut down upon it and perform the operation of radical cure. As we have just finished, in the course of our didactic lectures, the subject of hernia in general, I shall avail myself of this case to impress upon you some of the leading points in regard to the operations for the cure of ordinary reducible herniæ.

The object in all of the operations is to obliterate the hernial sac, to occlude the ring, and thus to prevent the descent of the hernia. It is impossible to even mention all the operations that have been devised for this purpose. They are innumerable, and have been employed for many years. The operation that I have generally found to be best, is ligaturing the neck of the sac, dissection of the extra-peritoneal part, stitching the stump of the sac to the ring, and finally the ring itself. The wound can then be closed or left open to granulate. I have found after the operation for strangulated hernia the use of a plug of the omentum, stitched into the canal, a most useful adjuvant. The patient after any of these operations should wear a properly fitting truss, in order to lessen the liability of a return of the hernia. If you do any operation for radical cure, use every possible precaution to protect your patient against septic infection of the peritoneum.

FLOATING KIDNEY.

The third case that I have to operate upon in the clinic to-day, is one of unusual interest. It is a case of movable kidney. This condition is found in women more frequently than in men, and especially in women who have borne children in rapid succession. The right gland is said to be affected in the proportion of twelve to one. This patient has been afflicted for four years with a mobility of the right kidney, and for the past two months has been a great sufferer. She complains of pain in the right loin, associated with a continuous sense of weight. She is conscious of something moving about in her abdomen. She has severe paroxysms of pain, resembling nephritic colic in intensity, and radiating in the direction of the lumbar plexus. This abnormal condition is accompanied by great languor and weakness to such an extent that for the past four months she has been unable to work. Attacks of vomiting and intestinal disturbance, with development of flatulence are very frequent. Whenever she attempts to move about she suffers great inconvenience. Rest in the recumbent position gives her only temporary cessation from pain and discomfort.

The physical signs present in this patient are: 1. A tumor that is freely movable, and possessing renal contour. 2. A tumor which upon manipulation causes the patient a sickening sensation. 3. A tumor that can be easily returned into its retro-peritoneal place. 4. A tumor, the situation of which is largely influenced by respiratory movements, and by attitude of the patient. 5. A tumor that shows no tendency to enlargement.

The differential diagnosis between the movable kidney and ovarian cysts, pancreatic cysts, and enlarged gall bladder has been made. The condition of the urine is wholly negative. In regard to the treatment in this case, as all other means of a palliative nature have failed to afford her relief, the operation of fixation of the kidney is indicated. I shall therefore proceed at once to suture the kidney to its anatomical place, an operation termed nephrorraphy. If the kidney is healthy, as there is every reason to believe in this case, nephrorraphy should be performed, but if the movable kidney is diseased, with the other kidney healthy, then a nephrectomy or removal of the diseased kidney should be performed. As the patient is fully anæsthetized, and as the parts have been made aseptic, I shall begin at once by making an incision a little below and parallel to the twelfth rib. The lower margin of the kidney on the right side is on a level with a transverse line passing through the center of the umbilicus. A vertical line drawn from the center of Poupart's ligament upwards to the ribs would divide the kidney so that one-third of it would be on the outer side, and two-thirds upon its inner side. The right kidney, on account of the liver, is situated a little lower than the left kidney. Instead of the lumbar incision another can be made by the anterior operation, which necessitates opening the general peritoneal cavity.

Having now cut through the integument, fascia superficialis with its two layers, the external oblique, latissimus dorsi and internal oblique muscles, I have

now come down upon the lumbar fascia, and the edges of the quadratus lumborum and erector spinæ muscles. I now pass my finger, rendered thoroughly aseptic, into the retro-peritoneal space. As the house-surgeon makes pressure backwards and upwards upon the front of the abdomen, I can feel the kidney, which is freely movable. With a curved needle and cat-gut suture I now pierce the capsule and a little of the renal substance in two places, and stitch the gland to the deep muscles and lumbar fascia. I shall place a second stitch, so as to be sure that the kidney will not become detached from the place to which it is anchored. The upper part of the incision is now closed by a continuous cat-gut suture, while the lower half of the wound is kept open by packing with iodoform gauze. Lloyd has suggested as an improvement to Hahn's operation to slit open the capsule, and pass the needle through the substance of the kidney. It seems to me that a medium between these two extremities, as suggested by Mr. Bruce Clark, is the better method, and that is to pierce the capsule and penetrate for a slight distance only the kidney substance.

This operation has not met with uniformly satisfactory results. In those cases of movable kidney where all palliative means have failed, the surgeon is justified in performing this operation, having first explained to the patient the possibility of its not effecting a permanent cure.

Inasmuch as the mortality of nephrectomy is about forty-two per cent., and that of nephrorraphy is about six per cent., the latter operation should always be performed when it is practicable. In eighteen cases of nephrorraphy collected by the late Dr. Gross, only one proved fatal; but in four of the cases nephrorraphy failed to give the expected relief, and in three of the cases the result was only partially successful. Mr. Lawson Tait, whose experience in this department of surgery is entitled to the greatest respect, said at the meeting of the British Medical Association, that "none of his patients have been benefited by the operation." and that he lost one patient from "circumstances which might be fairly attributed to the operation."

There are, however, other surgeons, whose opinions are entitled to the same respect, who believe that nephrorraphy affords relief to patients suffering from movable kidney.

In regard to the propriety of performing nephrorraphy in any case, it is always best to consider each special case by itself and upon its own merits. If you think that the operation can give the patient comfort and immunity from pain it should be performed when any reasonable assurance can be given that the operation may effect a radical cure. I have another case of movable kidney, and shall do this same operation again in a few days, and we can then observe together the progress of these two cases, and see whether or not the operation is one that commends itself to our judgment.

In conclusion, gentlemen, I want to call your attention to two cases of amputation of the thigh which have been recently performed in the clinic, for sarcoma of the tibia. One patient, a teacher, is an aged man, who injured his tibia by striking it against a school bench. The other case is that of a child who was hit upon the tibia by a stone thrown by a boy. The point I wish to impress is that traumatism in bone may cause sarcoma of bone, the only primary malignant tumor of bone. In the didactic lectures upon tumors, I shall again direct your attention to this clinical fact and show you many interesting specimens to illustrate the etiology of sarcoma.

The last case to-day is one of great interest to you, since it demonstrates the possibility of recovery in a case of pyæmia. This patient had his knee-joint filled with pus, as a symptom occurring in pyæmia. He had a very rapid pulse, temperature 105° F., sweats, intercurrent chills, etc. I opened and drained his knee-joint in your presence.

ATROPHY, HYPERTROPHY, AND DEVIATION OF THE SEPTUM.[1]

By CARL H. VON KLEIN, A.M., MD.,
OF DAYTON, OHIO.

OF all deformities to which the various parts of the human body may be subject, those of the nasal septum are among the most common. In the few years of my exclusive practice on the respiratory organs I have taken great pains in observing the septum in its various states.

I have examined the nasal cavities in over six hundred patients, and found not more than 2 per cent. to have an absolutely straight division of the nares. I might almost say that in every case I observed deformities of some sort, either atrophy, hypertrophy, or deviation of the septum.

The causes which are most common to deviation of the septum occur to people when they are in their babyhood. It is a common thing for a child, when it commences to creep and walk, to fall, and, nine times out of ten, on its nose. Many fall into cellars and down the stairs; the mother, aroused by the child's cries, hurriedly runs to its assistance and finds the little one bleeding at the nose; she wipes it carefully and bathes it with cold water until the bleeding ceases and the child is quieted; but it does not occur to her that the little, delicate septum might have been broken or injured.

It passes without notice until the child grows to man or womanhood, when he or she notices that their breathing is impaired, They consult a physician. He makes an examination of all the respiratory organs, but finds everything normal until he reaches the nose, when he says, "My friend, your nose is broken." "What!" exclaimes the patient; "I never had my nose broken that I know of." Nevertheless, the physician stands to his observation.

I have had many who left my office with disgust,

[1] Delivered before the American Rhinological Association, Chicago, October 9, 10, and 11; and by request before the Southwestern Ohio Medical Society, Cincinnati, October 9 and 10, 1889.

imagining I knew nothing about it, while others were but too glad to have their difficulty adjusted.

I but a short time ago operated upon a young man who had his septum crushed into one mass, of which he knew nothing. He claimed that even his parents could not remember of any fall or stroke he ever received. However, it was visible to himself, when he dilated his nose with my long-handled nasal speculum and looked into a mirror. This case is only one instance; but I may assert that in most cases that come under our observation either atrophy, hypertrophy, or deviation of the septum has had its origin from infancy.

There are other causes that might occur in the aged—a stroke or a fall—but they are very rare.

Not long ago I treated a case of deviation of the septum where a father taught an eighteen-year old son to box; he accidentally struck him on the nose. The young man bled, the bleeding was checked, but no attention was paid to it, until two years later, when at college, the young man commenced to complain about his eyes. An oculist was consulted, who found the difficulty arose from an injury to the nose. The case was then referred to me.

I found deviation of the septum, which I had no difficulty to adjust, and the young man entirely recovered from the affection of his eyes.

As to the atrophic or hypertrophic[1] state of the septum, though most cases, as stated above, occur from a stroke or a fall, yet there are some of atrophic septum which are caused by a simple hard blow upon the nose. A person takes a severe cold, and he Schneiderian membranes become inflamed to such an extent that the blowing of the nose is almost impossible. Then a persistent and severe blow of the nose may cause the breaking of a nerve or bloodvessel near the septum, which cuts off in part, if not in all, its nourishment. How many times have we seen men blow their nose persistently until blood appeared, and no attention was paid to it but simply the remark made, "I have a bad cold."

I have seen an atrophic septum as thin as paper, almost transparent, and by introducing a finger I could fluctuate it with the utmost ease, but nothing could be detected as to the prime cause. My own observation leads me to believe that atrophy of the septum is confined to the cartilaginous portion. Hypertrophy, I believe, is confined to the osseous portion, and is generally caused by injuries that occur to any other part of the bony system.

Hypertrophy of the septum generally commences with an ostitis, just as a stroke or a fall on the tibia or femur produces an ostitis, and subsequently hypertrophy. The most common form of atrophy and hypertrophy of the septum is the latter. The cartilaginous is not so liable to injury as the osseous part, from the fact that the cartilage is flexible, especially in young children. In over two hundred cases of hypertrophy and atrophy which came under my observation, the latter did not exceed 25 per cent.

In examination for deformity of the septum, I use nasal speculums or dilators of my own device,[1] which

FIG. 1. FIG. 2.

are of two different designs, as shown in Figs. 1 and 2, each being of two sizes. The lesser is for children and the greater for adults; with them the patient can dilate his own nostrils to his own satisfaction, and without the slightest inconvenience to himself or annoyance to the operator, as shown in Fig. 3. (See page 701.)

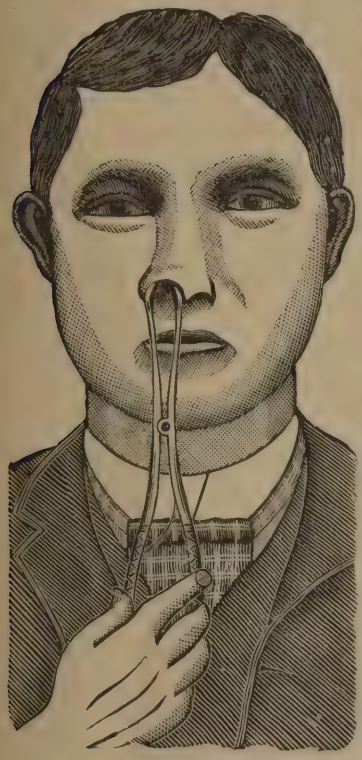
The patient introduces it with the right hand into the right nostril, and with the left hand into the left nostril, and the more he closes the hand or presses the handles together, the more he dilates the nose. All nasal dilators now in the hands of physicians that are made either with a thumb screw or a spring to make them self retaining are unreliable. A dilatation to such an extent as will make the instrument self retaining will stretch the membranes the whole length of the prongs and make it appear as though there existed an elevation and a hypertrophy. Especially when the cartilaginous part of the septum is flexible,

[1] All terms of hypertrophy in this article have reference to osseous hypertrophy only, including turbinatus.

[1] Figs. 1 and 3 were described some time back in this journal; Figs. 1, 2 and 3 in the *Journal of the Amer. Med. Ass'n.*

it will make the septum appear crooked. In fact, I believe dilatation is unnecessary; to keep the nasal lips apart is all that is required. Where the membranes are stretched they change in color; consequently you cannot recognize the real condition.

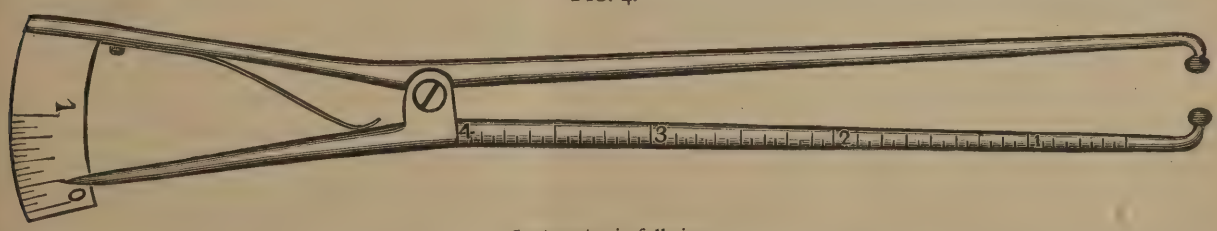
FIG. 3.



There are also cases where the membranes are so tender that prongs cannot be introduced into the inner part of the nose without severe pain. In such a case I would use an upright blade dilator, with which I dilate the nasal cavity without covering any part of the inner membranes of the septum.[1] The blades are turned parallel with the handles so as to enter the extended part of the nose, thus causing no obstruction to the parts where an examination is necessary.

In examination of the nares it is also essential to measure the thickness of the septum, and to locate at what distance the hypertrophy or atrophy exists, and to what extent. For that purpose I have devised a septometer, with the scale on one of the bars. It can enter the nose divided by a sixteenth of an inch, showing the depth inserted, while the lower index designates the thickness at each position that it is introduced. (See Fig. 4.)

FIG. 4.



Septometer in full size,

Deviation of the septum may be of the cartilaginous part, of the osseous, or both. I have never seen two similar deviations, they vary in every case. However, the treatment is alike, and may be confined to one of two methods, each method depending on the situation and extent of the deviation.

Whenever the deviation is in the bony part, or in a thick cartilaginous septum, the punch is indispensable, but when the deviation is confined to the cartilaginous part alone, and it is not very thick or atrophic, the deviation may be corrected by a simple hard plug inserted on that side of the nostril where the division is smaller. The nasal punches must be varied, in accordance with the shape of the deviation. The operator should make particular note whether the deviation is oblong, lateral, horizontal, vertical or otherwise. Then he must judge the necessary shape of the knives of the punch. If the deviation is inclined to be horizontal the knife of the punch must be horizontally longer; if vertical the knife must be vertically longer.

The knives of the punch must always be placed upon the convex, or extended sides of the nares. The plugs should be from one to two inches in length, and in thickness according to the size of the nares, shaped wedge-like and oval on both sides. On the outer end they should be cut at an angle, the longer point being blunt so as not to cause pain from sharp edges, and to fit within the pocket of transverse furrow of the nose. They should be made of ivory, black ebony, hard or vulcanized rubber.

FIG. 5.

Three sizes of nasal plugs.

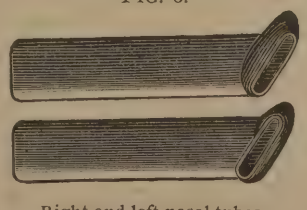
In bilateral or trilateral deviations it is necessary to plug the nostrils on both sides of the septum.

In such cases the solid plugs cannot be applied, as they cut off breathing. I therefore intubate the nostrils with silver tubes of my own design, and partly the same in shape as my plugs.

The part of the tube that goes against the septum is flattened, the outer side being oval, the front edge cut at an angle, and there being on the outer side an extended oval lip, to rest against the naso-labial furrow. This prevents the tube from slipping out and the patient breathes through it as freely as ever.

In a thin cartilaginous deviation where the septum is flexible I simply intubate on the narrower side of the nares, and let the patient wear it for a period of five or ten weeks. The tubes and plugs must be removed at intervals and cleansed with an antiseptic solution. This rule must be observed in all cases of intubation or plugging of the nares, irrespective of whether the septum is fractured or not.

FIG. 6.



Right and left nasal tubes.

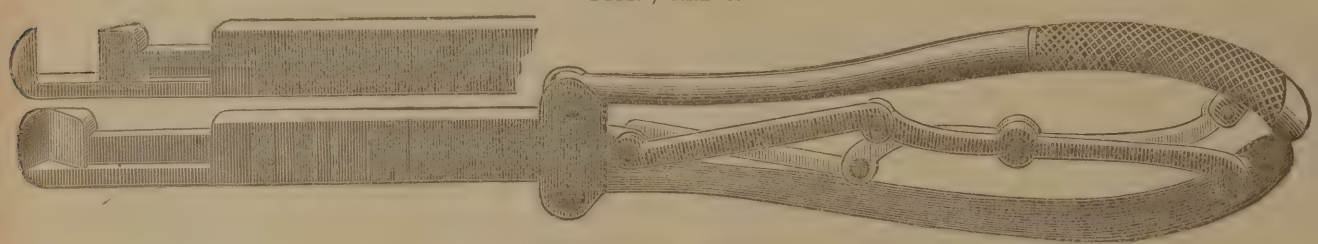
In an atrophic septum without deviation, there is nothing to be done, and the less the physician does with it the better for himself and patient.

[1] The instrument is shown in Fig. 2.

Atrophy, as stated above, is caused by a destruction of some nutrient supply, either of the nerve or blood; it is therefore an absolutely permanent injury. The treatment of hypertrophy of the septum depends entirely upon the space and on the size of the cavities of the nose. If the hypertrophy is insignificant, and the opening is large enough to admit free breathing, we are not justified in removing it, as it can be easily relieved by preventing a further growth. This may be done by dividing the tissues down to the bony surface, cutting through the vessels. The cut may be made laterally, either with a knife or an electro cautery. I prefer the cautery, as the operation may be done without hemorrhage. If the hypertrophy is so great that it impairs the breathing, the removal of it is absolutely necessary, but not with the cautery or the brutal saw. I object to the cautery because it destroys the membrane. The removal of the membrane of the septum a quarter to a half inch is too much to heal by granulation. It will leave the part bare.

The sloughing of such a wound is so great that it is liable to destroy the membrane of the entire side of the septum. Furthermore, I have seen several cases of erysipelas caused by the use of the cautery on the septum. The nasal saw, though not so dangerous, is yet the most inhuman instrument ever applied to suffering humanity. In addition to the severity of the operation upon the patient, the nerves of the operator and bystander are shaken by the sound of the saw. I have therefore devised a pair of nasal bone forceps, with which I can remove a hypertrophy with just as much rapidity as with the cautery, and without the destruction of the membranes.

FIGS. 7 AND 8.[1]



Nasal Bone Forceps.

The forceps are half-inch vertically, and an eighth of an inch in thickness; the barrel is three and a quarter inches, and the whole length of the instrument is about eight inches. The distant blade being stationary, the fore blade moves to and fro by opening and pressing the handles together. Both edges of the stationary and movable blades are formed like a chisel on the one side and on the other they are flat. It is easily introduced clear to the post nares, on account of its slight thickness and width. It can be opened to the width of an inch and a quarter, sufficient to go over any extended part that may occur on a nasal septum. The flattened side must be placed against the septum, and with the opening upwards, so as to cut off the hypertrophy, leaving the latter to hang upon the membrane. Then, by taking hold of a nasal or artery forceps, the hypertrophy can be turned out from the membrane, leaving the membrane hanging as a curtain, to be pushed back and spread upon the septum with a scalpel handle or something of the sort. It will adhere to the septum in a very short time.

In thirty-two operations for hypertrophy of the septum which I have performed with this nasal bone forceps, in none have I had the slightest destruction of membrane.

[1] Fig. 7 is a section of the left barrel, partly open; Fig. 8 is the complete instrument, closed.

ANTISEPTIC SURGERY IN THE COUNTRY.[1]

BY JOHN B. WHEELER M.D.,
BURLINGTON, VT.,
Professor of Clinical and Minor Surgery in the University of Vermont.

THE desirability of good antiseptic work is admitted much more generally than its practicability. It is all but universally acknowledged that the surgery of the last fifteen years is indebted to antisepsis for the remarkable advances which it has made. But to judge from what is sometimes said at society meetings, and printed in communications to medical journals, there is an impression among many members of the profession that it is impossible to do antiseptic surgery in the country; that the apparatus required is too cumbrous and elaborate, and that the details of operation and dressing are too numerous and complicated to be of practical use in the rough and ready work which the exigencies of country practice demand. This paper, therefore, does not undertake the superfluous task of defending antiseptic surgery, but attempts to show that such work is as practicable in a backwoods shanty, twenty miles from anywhere, as in a metropolitan hospital.

In the first place, let me make the statement that antisepsis is nothing more nor less than surgical cleanliness—cleanliness of operator, assistants, patient, instruments and dressings. By surgical cleanliness is meant the complete absence of what we commonly understand by dirt, and, moreover, the complete absence of the germs whose development produces suppuration and the various diseases which may result from wound infection. These germs may exist in great numbers upon a surface which, to our unaided senses, appears perfectly clean, but is not so in reality until the germs have been destroyed by the action of some germicide. The working maxim is that while an object which is apparently dirty cannot be surgically clean, an object which is apparently clean may be surgically dirty. It follows from this

[1] Read at the annual meeting of the Vermont State Medical Society, October 11, 1889.

that we must carefully and thoroughly remove all dirt by the ordinary methods, and carefully and thoroughly destroy all germs by the use of germicides. He who says that nothing but simple cleanliness is necessary to insure the best surgical results, and he who says that cleanliness is unimportant if disinfection is thoroughly practised, are alike at fault. We need both the scrubbing-brush and the antiseptic solution.

Perhaps the best way of showing how surgical cleanliness may be practically attained, is to describe in detail the manner of conducting an operation in any house remote from city conveniences. Suppose that the surgeon has an emergency operation to deal with, at a place many miles distant from his own house, and that the patient is poor, as frequently happens in such cases. The first thing which claims attention is the surgeon's outfit. For this sort of work it must be efficient, portable, thoroughly antiseptic and as cheap as is consistent with efficiency. In addition to such instruments as are requisite for the operation in question, the surgeon will take with him a fountain syringe, a couple of yards of rubber cloth, an apron, a razor and nail-brush, tablets of bichloride of mercury, a few ounces of carbolic acid, iodoform, Lister's protective, drainage-tubes, silk, cat-gut, carefully disinfected sponges, gutta-percha tissue, gauze and absorbent cotton impregnated with bichloride of mercury, gauze bandages prepared in the same way, plain absorbent cotton and a paper of safety pins. A can of ether completes the outfit.

This seems like a long list, but the articles are obtainable at small expense, and can all be easily stowed in a hand-bag of moderate size.

On arriving at the scene of operation, the surgeon's first care is to cleanse and disinfect his hands by carefully scrubbing them up to the elbows with a nail-brush, until they appear perfectly clean, especially under the nails, and then soaking them for a minute in a bichloride of mercury solution, of the strength of 1–1000. After this he makes such examination of the patient as may be necessary before etherization, taking the utmost care not to touch any open wound unless his hands are thoroughly antiseptic. He then makes the solutions for operation, a carbolic acid solution for the instruments, and a bichloride solution for use in and about the wound. A quart or two will be sufficient quantity of the carbolic solution, which is made of the strength of 1–20, and poured into some platters and saucers obtainable at the house, or in the neighborhood. In these platters and saucers, which must be perfectly clean, are placed the instruments, the threaded needles, the cat-gut and silk cut into ligatures, safety pieces, a piece of drainage-tube and the Lister protective. The non-corrosiveness of the carbolic acid solution is the reason for its employment as a bath for instruments. The solution of bichloride of mercury, the strength of which varies from 1–2000 to 1–5000, is made by dissolving a sufficient number of bichloride tablets in warm water. Two or three gallons of this solution should be made. The pitchers, bowls, or whatever the solutions are made and kept in, should be perfectly clean, and the bichloride solution should be strained through clean cloth before being used, in order to get rid of the slight sediment which remains after dissolving the tablets. The fountain syringe is then filled with the bichloride solution and hung up where it can be conveniently used for purposes of irrigation during the operation. Some of the remaining solution is poured into two bowls, one of which is to be used for rinsing sponges and the other for disinfecting the operating towels and the hands of the surgeon and his assistants. The operating towels are such towels or clean cloths as the neighborhood affords, a few of which are immersed in the bichloride solution, and before the operation is begun are wrung out and used to cover everything in the immediate vicinity of the field of operation. During this time the patient has been anæsthetized, and may now be put upon the operating table, which can be very satisfactorily extemporized out of an ordinary kitchen table and a small stand. If these, or some equivalent articles are not to be had, the surgeon must do the best he can on the bed where the patient is already lying. The rubber sheet is then fastened around the part to be operated on in such a way as to keep the rest of the patient from getting wet, and to conduct the irrigating fluid into a pail on the floor. The whole field of operation is thoroughly scrubbed with the nail-brush and then shaved. The razor is used to get rid of hairs which might fall into the wound and infect it, and also for the purpose of removing dirt. The amount of dirt which appears in the lather after closely shaving an already clean looking skin is surprising, and efficiently demonstrates the necessity of using the razor on any part of the body. The surgeon and assistants then give hands and arms a final scrubbing and disinfection, and the whole field of operation is thoroughly irrigated with the solution in the fountain syringe. After this process the skin may be regarded as surgically clean and fit to work upon. The towels which have been soaking in the bichloride solution are wrung out and spread around the field of operation, in order that the operator, when he happens to lay down an instrument or rest his hand on the table, or the patient's body, may touch nothing but the disinfected towels and thus avoid contact with anything which might be a source of infection. During the operation irrigation is used more or less frequently, according to the amount of blood to be washed away and the liability of the wound to infection. Before sewing up, the wound is thoroughly flushed with the irrigating solution, and then is sponged dry, in order to avoid mercurial poisoning, which is liable to occur if a quantity of the solution is left standing in the wound.

The greatest care is taken throughout the operation to avoid the introduction of septic matter into the wound. If the hands of the surgeon or his assistants touch anything that is not surgically clean—clothing, furniture, &c.—they are disinfected anew before approaching the wound or touching instruments, sponges, ligatures or dressings. If an instrument touches any object that has not been rendered aseptic, that instrument is disinfected again before being used. If it falls on the floor, it is carefully scrubbed and disinfected before used. If a sponge falls on the floor, it is thrown away, as unfit for further use.

The operation is concluded by inserting the drainage tube and sewing up the wound (supposing the case to be one where healing by first intention is desired). The line of incision is then dusted with iodoform and overlaid with a piece of Lister's protective, in which a hole is cut for the drainage tube to come through. Then come the dressings, consisting of a few handfuls of bichloride gauze, over which is placed a huge mass of bichloride cotton, which is held in place by a bichloride gauze bandage. A very thick, bulky dressing is necessary, in order to provide an antiseptic receptacle for the fluids which drain away from the wound. If the dressing is small, it quickly becomes soaked with drainage, which soon decomposes on coming in contact with the air. This necessitates the undesirable step of an early change of the dressing, in order to avoid the still more undesirable complication of suppuration, or something worse.

In applying the dressings, they are handled as little as possible, and of course only with surgically clean hands. The best way is for an assistant to bring the receptacle which contains the dressings, open it and let the surgeon take out what he wants. In this way the dressings are touched by no hands but the surgeon's.

It is not claimed that the foregoing description covers all the latest ideas in antiseptic technique. It is intended merely to give the details of a method of doing antiseptic work, which is practicable in country surgery, and not to give a resumé of the most recent progress in antiseptics. Nothing has been said, for instance, of the disinfection of instruments by heat, because it cannot, so far as it has been tried, be carried out so thoroughly in the country as in a hospital. But I speak from experience when I say that the method of operating above described can be practiced amidst the most unfavorable surroundings, and with excellent results—no infectious diseases, no suppuration, but healing *per primam* almost the invariable rule in all incised wounds. It is not claimed that there can be no better way of operating antiseptically. Any method which is simpler and more thorough, ensuring greater perfection of cleanliness and disinfection, is better. This is offered as a method which, by the use of antiseptics of known and proved value, and of materials and apparatus easy for any practitioner to obtain, will give first-rate results, if faithfully and thoroughly carried out. The choice of an antiseptic, of antiseptic apparatus and of materials for dressing, is comparatively of minor importance. If the surgeon has a horror of dirty finger-nails, filthy instruments, and an unscrubbed field of operation, and if he abominates the idea of approaching a wound with anything which is not surgically clean, he will do good antiseptic work, in whatever way he goes about it.

THE CAUSE OF FATHER DAMIEN'S DEATH.—It is positively stated that the immediate cause of Father Damien's death was an attack of pernicious malarial fever, which his constitution, undermined by leprosy, was unable to resist, and for which he could not be induced to take any remedy. Father Gregory, one of his fellow-workers, died at the hospital of Kakaako, a confirmed leper, last January.—*British Med. Journal.*

The Polyclinic.

MEDICO-CHIRURGICAL HOSPITAL.

GASTRIC CATARRH.

THIS patient, aged thirty-eight years, laborer, has complained of dizziness for the last two weeks. One day he completely lost consciousness while working at his bench. He has no headache, no numbness or paralysis, and his eye-sight is good. Last week he had some bleeding at the nose. He used to drink three or four glasses of whiskey every morning before breakfast. He has a tender stomach and at times it becomes distended with gas; there is a bad taste in his mouth in the morning, but he does not vomit. The bowels are moved once a day, and the appetite is good. He has had a slight palpitation of the heart for the last ten years. His liver is slightly larger than normal. These attacks of dizziness and gastric trouble would lead one to look for cirrhosis of the kidney, which may cause uræmic poisonsoning. The urine is clear, normal in quantity, and without albumen. The bleeding at the nose is a common symptom of cirrhosis of the liver. The tongue is small, pointed, and quite furred, while the edges are moist. Hence, this is simply a case of gastric catarrh, which may easily account for the heart and brain disturbance, as well as the furred tongue. Temporarily we may lay aside the consideration of Bright's disease. The moderate enlargement of the liver may be the beginning of a hypertrophic cirrhosis. He drinks too much coffee. Everything seems to be swimming before his eyes, but on closing them the vertigo disappears; this is an *objective* vertigo. The use of purgatives will help him, so we will give him a pill of rheum and podophyllin. The palpitation of the heart is referable to the stomach, hence we will need only to regulate the diet. As he has bulimia we will restrain his appetite and ask him to follow the French custom—not to eat a full meal.—*Woodbury.*

NEURASTHENIA.

This young woman comes to us complaining of a constant headache. She has lost her appetite during the last week; has noticed some blood in her mouth in the afternoons, but never in the mornings or evenings. She complains of heat in the back of the head; does not drink tea or coffee, and eats a light breakfast and supper. She has not been able to work since July. The blood in her mouth amounts to a teaspoonful each time, and appears all at once. She has no cough and has lost no flesh during the past year. She cannot sleep at night on account of nervousness. The lungs show little or no disorder. The heart is nervous, but there is no valvular disease. Her eyes have been examined and she was recommended to wear glasses constantly; but as she has not worn them, the pain in the head may arise from this defect of refraction. She is suffering from neurasthenia. All that can be hoped for is to keep her functions as active as possible; but she will always be subject to headache and pain in the back. I may

express it in this way: her outgo of energy is below the income.

We will treat her with kindness and put her under physiological conditions and restraints: give food to build up the nervous system, along with the syr. hypophosphat. comp. with strychnine. We will recommend a good breakfast of bread and milk in preference to oatmeal. Let her also take this for supper, and in addition a poached egg. She should drink milk mixed with lime-water to prevent acidity. As she is usually constipated, let her use Aunyadi water, or Crab Orchard salt, which has the following composition:

℞.—Ferri sulphatis . . . . . gr. ij.
Potassii et sodii tartratis . . . . . ʒ ij.
Magnesii sulphatis . . . . . gr. xx.
Aquæ . . . . . O ij.
M.—Sig. A wine-glassful every morning.

—*Woodbury.*

EMBOLISM.

This man was here during the preliminary session and was paralyzed on the right side of his body. He was unable to feed himself or use his leg. You can see that the temporal arteries are larger and more tortuous on the left side than on the right. His eyesight is good. At first he saw everything double, but this is not the case now. He has no headache He lost the power of speech and was unable to talk for some time, but now he has regained it somewhat. There are some words that he cannot remember. The nutrition of both sides of the body is good and about equal. He has an extensive lesion of the mitral and aortic valves. His whole trouble has been caused by an embolus affecting the arteries of the brain. This embolus has either been absorbed, or the collateral circulation has been freely established.

At the present time it is proper to use electricity, but never in the earlier stages of the trouble, for fear of causing central irritation. Strychnine, one-sixtieth grain three times a day, is administered. We will continue to give him warm baths, and apply electricity twice a week.—*Woodbury.*

It has been observed that puncture of the floor of the fourth ventricle of the brain produces an increased flow of saccharine urine. Puncture below it produces an increased flow of non-saccharine urine.—*Woodbury.*

Do not remove a gland until you are sure the whole thing is broken down and ready to be thrown off.

—*Garretson.*

PHILADELPHIA HOSPITAL.

PHTHISIS PULMONALIS.

FOUR years ago this man had acute articular rheumatism, with heart complication. He suffered from palpitation and dyspnœa on exertion. Last March he took a bad cold and coughed up much sputum, mixed with blood. He now has night-sweats, loss of weight, but no diarrhœa. He has lost thirty pounds in the last two months. On October 24 he had a hemorrhage from the lungs, which amounted to fʒiv. On October 31 he had another slight hemorrhage. At the present time he is not spitting blood. Left apex of the lung is markedly dull, but the right side is slightly super-resonant. While breathing, the intercostal spaces, tip of the ensiform cartilage, and epigastrium are perceptibly drawn in. There is a harsh respiratory murmur, with marked crackling and bubbling sounds. Hence, there are cavities in the left lung. The patient is undoubtedly affected with phthisis. He has a pronounced systolic mitral murmur due to regurgitation. It is exceedingly rare to find mitral regurgitation along with phthisis more marked in the left than the right lung. Hæmoptysis may be caused by constriction of the mitral valve, but in this case I think it was due simply to the ulcerative process of the disease. The treatment of hæmoptysis is simple, yet one of the most important subjects in the whole range of medicine. First, and foremost of all, there must be absolute rest and quiet; next, an application of turpentine by means of a towel—not a stupe, for that, being warm, will do more harm than good. Turpentine internally is excellent. Ergot is almost always given, but it has little effect if the hemorrhage be profuse. If it is capillary ergot is invaluable. The next thing that you will give is opium, to quiet the cough and put the patient to sleep, thus maintaining quiet and rest. Gallic and tannic acids, acetate of lead, and other systemic astringents are not available, for they turn the stomach, destroy the appetite, and act far too slowly. When I have a stubborn case I use the oil of erigeron. When this fails I use:

℞.—Lycopi Virginici . . . . . ʒj.
Aquæ . . . . . Oij.
Fiat mistura.
Sig. Take a wine-glassful every hour 'till relieved.

A chill will staunch the blood, but the following reaction and fever will bring on a more violent attack; hence, the application of ice packs does more harm than good. Never apply ice longer than fifteen minutes at a time, and never at shorter intervals than three minutes when you do use it.—*Curtin.*

PARENCHYMATOUS TONSILLITIS.

One week ago this man had a chill, and complained of sore throat and a sensation of swelling or fullness that interfered with his speech and breathing. The lymphatics are now swollen, and there are two enlargements in the pharynx, which, from the history, prove to be due to a parenchymatous tonsillitis. Deglutition is almost impossible, owing to the close approximation of the glands. This will go on to suppuration in time. We will make a free incision on the worst side, cutting upward and inward, with a protected knife. Hemorrhage is rather free for a short time, but this is what is desired in order to deplete the parts. Danger of delay is considerable, as the abscess may break and cause death by strangulation. Gargle the throat with an antiseptic solution. Listerine or boric acid, used every half hour, is good. We will give this patient a gargle containing one part of listerine to three parts of hot water. He should apply a poultice to the angle of the jaw, to prevent cold.—*White.*

GONORRHŒAL RHEUMATISM.

This man has a history of gonorrhœa, with a sudden swelling in his left ankle-joint and right wrist. He supposed it to be an ordinary rheumatism, but we recognize the gonorrhœal form. The treatment consists of potassium iodide, gr. x, gradually increased. Oil of gaultheria has afforded some good results. Blistering was done over the swelling, and a rubber bandage applied as a support. The treatment of these cases is very unsatisfactory. They usually last from four to ten days, and in some cases may run on for months, finally crippling the joint. You will find that by the use of the following prescription, with other remedies, your patients will soon be able to get about :

℞.—Liquor. plumbi subacetatis . . . . ℥j.
Extracti belladonnæ . . . . . gr. x.
Extracti opii . . . . . gr. x.
Misce. fiat unguent.
Sig. Apply locally to the joint.

Sometimes the swelling will leave a joint suddenly and appear in another part. In my early practice a young man came to me with an inflammation limited to the knee-joint. I did not suspect the true cause and put him on the salicylates, without any result. Finally, I allowed him to go out riding, and to use crutches. One day I was suddenly called to see him, and found that the inflammation had left his knee and that he was playing foot-ball, when his testicle became swollen and inflamed. He then told me that he had an attack of gonorrhœa and that he had been treating himself. The gonorrhœa left him, then it went to his knee, and finally to the testicle. I relieved him by the remedies mentioned, and he got well.—*Porter.*

URETHRAL FISTULA.

This boy is almost full-grown, and has a fistula in the penile urethra, a few inches back of the meatus. It may be the result of traumatism, abscess, or gonorrhœa. We will thoroughly freshen the edges of the fistula and pass through it two hair-lip pins, and throw about them a figure of eight ligature, and dress. We will tie a soft, rubber catheter in his bladder, and allow it to remain until the wound is healed. It gives him no trouble, save that the urine passes through the fistula when he urinates, unless he closes it with his finger.—*White.*

CODEINE.

Dr. Musser declared that codeine, in doses of one-quarter grain every three hours, was successfully used to alleviate abdominal pain, and is employed in preference to opium, which always constipates.

PENNSYLVANIA HOSPITAL.

IN fractured patella Morton uses a gut ligature to hold the segments together. But before approximating them, he lifts out of the space between the segments the fibers of the quadriceps femoris muscle which have fallen into it. Neglect of this procedure is the cause of many of the ununited fractures of the patella, since the segments will not unite when muscular fibers lie between them.

Morton presented a young man in apparently good health, who had an ununited fracture of the femur about four inches below the great trochanter. The fracture was converted into a compound fracture, the ununited ends were sawed off and the sawed ends coaptated with pins and wire. The compound fracture was then converted into a simple fracture with antiseptic procedure. Reparative processes, the doctor remarked, are materially interfered with by diabetes and Bright's disease. Hence, in all cases of fracture, he recommends an examination of the urine, that one might be on his guard as to prognosis and be better prepared to prevent the formation of a false joint. He who does this will have an advantage over him who does not.

JAUNDICE.

Meigs introduced a case of catarrhal jaundice. The patient presented a marked yellow discoloration of the skin. The attack came on suddenly ten days previous to his appearance in the clinic. Since being in the hospital he had been given the phosphate of soda in ʒj doses every four hours, which affected the secretions and acted as a gentle purgative. Under this treatment he improved. He had always been healthy, except at one time, when he had cholera. He had no evidence of a cardiac lesion. His liver was slightly enlarged, but the attack was too sudden to have been caused by any organic lesion of the liver, such as cancer or cirrhosis, etc., and he was not sick enough to be suffering from hepatitis. It may have been due to impacted gall-stones or catarrhal inflammation of the gall-ducts.

PLEURISY.

This woman came before the clinic complaining of pains in the chest. She was twenty-nine years of age, cook by occupation, and was very much addicted to tea drinking. There was dulness on percussion at the base of the left lung, absence or weakness of respiratory sounds, decrease of vocal fremitus ; hence, there was solidification in that part or pleural effusion. But in pneumonia we have bronchial breathing and increased vocal fremitus, while in a pleural effusion we have slight bronchial breathing and diminished vocal fremitus. Her trouble was evidently pleural effusion, and for that she was being treated.—*Meigs.*

A VIENNA surgeon has examined the air of operation halls, which had been saturated with eucalyptol spray, and finds that no development of bacteria cultures on gelatine takes place in them. According to these investigations, comments a contemporary, eucalyptol is to be regarded as an excellent disinfectant of the air, since it is harmless when inhaled, and does not destroy clothing or furniture.

—*Notes on New Remedies.*

AT the recent session of the Medical Society of Virginia, Dr. William F. Cooper, of Woodville, presented the report on materia medica and therapeutics, in which he says of amylene hydrate : "In doses of from fifty to seventy-five grains, it causes neither nausea, headache, indigestion, nor other unpleasant after-effects ; but more frequently than other hypnotics it induces refreshing sleep."

A PLEA FOR PEDIATRICS.

IF there be any one feature of modern medicine more pronounced than another it is the development of the specialties. Every organ has its special student; different phases of disease receive the attentions of different sets of investigators; and even special therapeutical measures seem to belong to some individuals more than to others. Not only is general medicine divided into surgery, obstetrics, gynæcology, ophthalmology, laryngology, otology, neurology and pediatrics, but even these are again subdivided; for the pathologist rarely devotes any attention to therapeutics, the electrician ere long becomes known as such only, and the student of inoculation seldom studies general diseases or their treatment. Medical science has become so vast that it is an absolute impossibility for any one man to grasp all of its details. If he be a practitioner he naturally falls into one particular line of work, led thither by his own inclination, or by the increase of his practice in that line as the result of a suddenly acquired reputation; if he be an investigator, he finds his greatest success in the devotion of all his energies to some one line of experimentation, whether it be with the microscope or with chemical reagents. Though all this has a tendency to narrow one's views and render them more or less one-sided, we think in the main it has its decided advantages. When we congratulate ourselves and grow enthusiastic over the recent advances and wonderful discoveries in medicine, we cannot but remember that they have all occurred since the development of the specialties.

The revelations of the microscope, the subtle manifestations of chemistry, and the improved facilities of the laboratory have enabled us to comprehend the nature of diseases more definitely, and so to apply to them the correct therapy. The simple empiricism of earlier days and the mere observations of general practice have never given the first impulse to medical advancement; they have merely proved and confirmed the value of the special discoveries. Hence, we are in favor of specialism when it is based upon a broad and general education. Not only do we rejoice in the earnest devotion of the pathologist, the physiological chemist, and the experimental therapeutist, but we congratulate ourselves upon the good work of the gynæcologist, neurologist, ophthalmologist and other specialists.

Of all the specialties, however, none receive our endorsement more heartily than pediatrics. We are surprised even that greater attention has not been given to this department of medicine than heretofore. There are many discouragements and drawbacks in the treatment of children, which, to some extent, may explain why there are not more specialists in this line of work. The difficulty in obtaining symptoms and arriving at a positive diagnosis, the uncertainty about the action of the drugs administered, the delicate susceptibility of the immature organism, the absence of reason and the childish impatience are at times exceedingly unsatisfactory and annoying. According to a large part of our medical literature, the care of children seems to concern only their feeding, and in glancing through some of our college announcements their study seems merely an attachment, as it were, of gynæcology and obstetrics. This is not as it should be, for we can well do without the other specialties sooner than that of pediatrics.

In an admirable address delivered before the First Annual Meeting of the American Pediatric Society (*Archives of Pediatrics*, November, 1889) the president, Dr. A. Jacobi, of New York, took as his subject, "The Relations of Pediatrics to General Medicine," and introduced some pertinent remarks in regard to this specialty. Unlike the adult, whose chief physiological function is the maintenance of life and the reproduction of the species, the infant's chief function is that of growth. This at a glance shows how different the general lines of treatment in both should be. The majority of the diseases of adult life have had their foundations laid in infancy. Anything that affects the growing function of the child will be certain to manifest its effect in later life. In regard to treatment in the adult this question of the development has no influence whatever. We try to modify the existing conditions for the present only in the adult, but in the child we are continually looking to a far distant result.

Furthermore "pediatrics does not deal with miniature men and women, with reduced doses and the same class of diseases in smaller bodies, but it has its own independent range and horizon." Certain diseases are found only in children, others have a special symptomatology of their own, while most of them respond to treatment in a way entirely different from that in the adult.

A large part of surgery belongs to infancy. Orthopædics is devoted entirely to children, while the

operations for hare-lip, congenital malformations of the anus and rectum, spina bifida, fissured palate, all demand special knowledge and skill. Osteotomy, tenotomy, tracheotomy, intubation, are mostly performed in children. Invagination occurs in twenty-five per cent. of all cases under one year, and fifty-three per cent. under ten. One has but to glance at the works of Guersant, Forster, Bryant, Giraldeà, St. Germain, and others to see how important a branch of medicine is the surgery of childhood. Nervous diseases are best represented in children as they have their beginnings there. Aside from heredity, the effects of childbirth and the rate of development, the amount of nutrition and hygienic care, and the numerous accidents to which children are subjected—are all more or less causative of the cerebro-spinal diseases, which occur both early and late in life. The pathology of the nervous affections has been more successfully studied in the young tissues of infancy, than in those of adults.

Psychology, the basis of the mental diseases, owes a large part of its interest and actuality to the study of the growing child. So impressible are the young that the causes of mental disturbance, such as chorea, hysteria, epilepsy, worms, fevers, rheumatism, anæmia, chlorosis and alcohol, are best exhibited in this time of life.

The influence of heredity may be almost entirely obscured in the adult, who has the power and will to control his acts and emotions, but in the infant it cannot be hidden. Malformations, specific taints, neoplasms of all sorts, begin to show themselves early in life when due to heredity.

Many of the constitutional diseases and infectious fevers belong especially to early life, or at least possess a special symptomatology at that time. The treatment is different in many instances, and for its successful application demands the keenest ingenuity on the part of the physician.

As the child is father to the man, so is infancy the germ of the future nation. Hence the question of nutrition, hygiene and morals in childhood, is of paramount importance for the future welfare of society; as the stability of the government depends upon the integrity of the family and home life, so the preservation of the national supremacy rests upon the proper care of the young. No small part of this care falls to the lot of the physician, hence if he is interested in the good of the community and is at all imbued with the spark of patriotism, he will feel an unusual interest in the subject of pediatrics. He will not only commend it as preëminently the specialty of specialties, but in his general practice he will give it particular attention; so that it will come to be said that every practitioner has one specialty at least, and that the highly interesting and all important one of pediatrics.—L. H. M.

PROF. ERNEST LAPLACE commences his course on Bacteriology as soon as the class reassembles after the Christmas vacations. Dr. Laplace has proved a very popular lecturer.

THE VIRGINIA EXAMINING BOARD.

IN the *Virginia Medical Monthly* for November may be found a very interesting report from the State Board of Examiners. The Secretary is to be commended for a report which is a model of its kind—being full, explicit and to be comprehended at a glance. The questions asked in each department are given, and the average obtained in each branch by each of the unsuccessful candidates, who are not mentioned by name, but by the college graduating them. The questions do not seem to have been unnecessarily severe—rather the contrary; on the whole they embrace little which every student ought not to be prepared to answer. Of 18 who failed to obtain the necessary average (75 per cent.), 12 passed in Surgery, 11 each in Practice, Obstetrics, and Hygiene and Medical Jurisprudence, 8 in Therapeutics, 2 in Anatomy, 1 in Chemistry, and none in Physiology. The applicants came from nine different colleges; hence we must infer that the last three branches are indifferently taught in all these schools, or else that the committees in charge were more strict in their requirements than those examining in the other sections. The questions do not appear more difficult than in the practical branches; in fact, those in Chemistry are probably the least difficult of all, excepting in Practice. Nor can this divergence be due to the grading of the college course, as not more than one of the schools named has established such a course. Such differences, however. cannot be helped, and the publication of this table should perhaps prompt the examiners in other branches to be a little more stringent in future, as it is difficult to understand how one can obtain a grade of 82 in Practice when he only received 20½ in Physiology.

Taken altogether, the work of the Board is so good that we would be glad to see it repeated in every State in the Union. This would enable the colleges to raise their standard of admission and graduation examinations. As it is now, a college is "successful" in proportion as her requirements approximate those of the lamented Dr. Buchanan.

—W. F. W.

A NEW CLOAK FOR VICE.

GOOD work has been recently done by the *Press* in ferreting out houses of ill-fame, advertised as places where massage, baths, and electric treatment are administered. The advertisements are bold, and some of them very suspicious looking. Establishments where baths may be obtained are usually kept for male or female applicants only, or else have certain days and hours assigned for each; but here were houses kept by women to which both sexes were invited indiscriminately. Of course the "treatment" was only a sham behind which were masking some of the worst forms of prostitution. So impudent were these advertisements that not only the young and unwary of the laity were invited, but

even physicians were recommended to come themselves and to send their patients for "treatment."

Massage and baths are among some of the more effective therapeutic resources known to medicine, and it is an outrage that they should be debased to the uses of these vultures of society to enable them to entrap more easily their victims. The medical science and art offer ample opportunity for one of an evil turn of mind to carry out his wicked schemes, hence the closest inspection should be exercised, and all houses pretending to afford medical treatment should be continuously watched.

Massage and baths need never be practised save by persons of the same sex as the patient. As methods of treatment they should be kept entirely within the province of the physician, and under his immediate direction. Many people indulge in cold plunges and showers, who are not physically able to endure such extremes, and are laying the foundations of some of the nervous troubles that appear later in life. Massage is a good thing in certain conditions of convalescence, but it should not be allowed to replace healthful out-door exercise and well-regulated gymnastics. There is some danger of these simple but beneficial means of treatment being abused. Neither massage, baths, nor electricity are panaceas, hence they should be recommended only by proper authority and in properly selected cases. There is no need whatever of a multiplicity of this class of establishments, and when such becomes the case they should be regarded with suspicion.

We hope the police authorities will leave no stone unturned in rooting out the evil disclosed by the *Press*, and they will receive along with this valuable daily journal the thanks of all law-abiding and upright citizens.

Annotations.

NON-TUBERCULAR HÆMOPTYSIS.

IN an address delivered before the Medical Society of London, and published in the *British Medical Journal*, Sir Andrew Clark gave the results of his study upon a form of non-tubercular and non-cardiac hæmoptysis occurring in elderly persons. He cites several instances of this variety of pulmonary hemorrhage, or arthritic hæmoptysis—as he ventures to call it—and after a brief consideration of its main characteristics, draws the following conclusions:

1. There occurs in elderly persons free from ordinary diseases of the heart and lungs, a form of hæmoptysis, arising out of minute structural alterations in the terminal bloodvessels of the lung.

2. These vascular alterations occur in persons of the arthritic diathesis, resemble the vascular alterations found in osteo arthritic articulations, and are themselves of an arthritic nature.

3. Although sometimes leading to a fatal issue, this variety of hæmoptysis usually subsides without the supervention of any worse anatomical lesion of the heart or of the lungs.

4. When present this variety of hemorrhage is aggravated or maintained by the administration of large doses of strong astringents, by the application of ice-bags to the chest, and by an unrestricted indulgence in liquids to allay the thirst which the astringents create.

5. The treatment which appears at present to be the most successful in this variety of hæmoptysis consists in diet and quiet, in the restricted use of liquids, and the stilling of cough; in calomel and salines; in the use of alkalies with iodide of potassium, and in frequently-renewed counter-irritation.

THE TREATMENT OF SCROFULOUS GLANDS.

IN an admirable article on this interesting subject, Dr. Frederick Treves presents, in the *Lancet*, the following suggestion:

He recommends that the patient be placed under the best hygienic surroundings possible, as the basis of all further treatment. He claims that special benefit may be derived from a long residence upon the sea-coast, especially where there may be found large quantities of sea-weed exposed to the action of the sun. It is needed, in addition, that sufficient attention be paid to the proper clothing of the individual, care being taken that the skin from the neck to the ankles and wrists be covered with wool. Iron, arsenic, cod-liver oil, and quinine should be exhibited in the usual doses, and iodine as found in the well-known Kreuznach water is often of benefit.

The local treatment should embrace a careful survey of the whole periphery, and any abrasion of the tissues from which the lymph-vessels run, should be carefully dealt with. Thus enlarged tonsils, scrofulous pharyngitis, affections of the mouth and teeth, coryza, ozæna, otorrhœa, phlyctenular ophthalmia, and eczema of the scalp, all of which are common causes of disturbance, must be rigidly treated. The glands themselves should be protected from all irritation and fluctuations of temperature. Local applications, such as iodine, compresses of sea-weed, and ointments are of but comparatively little value. The most important local measure consists in giving rest to the part. If operative procedures be considered, the earlier the operation be performed the easier it will be. The gland should be cut out, and not torn out. No drainage-tube should be employed if it can be avoided. After the operation the neck must be kept absolutely rigid for not less than ten days.

WE regret to note that the *Virginia Medical Monthly* reproduces some of the stupid answers given by rejected candidates for registration. No good can possibly accrue from such publication; but our friends across the ocean, ever ready to decry American science, will seize upon these items as illustrating the ignorance of the *typical* American doctor. Fools probably could be found, on close examination, in some other countries beside this; but they are wise enough to keep their folly out of the papers.

SEND us queries for "The Inquirer."

Letters to the Editor.

A PECULIAR CASE.

WILL you kindly insert the following notice of a peculiar case, in which all the nails of the fingers are involved, and one on the great toe of the right foot? The patient, male, æt. twenty-seven years, had a mild attack of psoriasis some four years ago, with recurrences on and off ever since, and localized now at a few spots situated in the back, between the shoulder-blades, and on the chest. The nail affection has persisted now for some four years, and seems to resist vigorously the most persistent treatment.

The nails are thickened, very brittle, opaque in several places, have a sulphur color, and are roughened. Recently, when I saw the case for the first time, all the nails were affected more or less, with the exception of that of the little finger of the left hand, which looked perfectly normal. In two weeks after, I noticed a change, which asserted itself in the formation of yellowish specks here and there in the substance of the nail, until in a few days the whole became involved. The nails, beside presenting the peculiarities mentioned above, also appear streaked with yellowish lines running longitudinally; the surfaces in several are uneven, and have a tendency to split up. The patient had been under treatment for the psoriasis, but his general health was otherwise perfect.

The nail affection was subjected to the following treatment for a long time: The nails were thoroughly scraped, and lotions of mercuric chloride (three, four and six grains to the ounce) vigorously rubbed over the surface, seemingly without effect. The use of arsenic (Fowler's solution) was also pushed. Now, what I would like to learn through the columns of this journal, is what must I do to permanently cure this stubborn affection. The patient's history is without reproach. There is no syphilitic taint; but, on the contrary, his general health and looks are superb. The disease is none other than *onychomycosis*.

I would be pleased to have the advice of some dermatologist upon the subject.

SEBASTIAN J. WIMMER, M.D.

ST. MARY'S, PA. Nov. 7, 1889.

INFECTED BOOKS.—The circulating libraries of Dresden have experimented upon the communication of infectious diseases by books. Soiled leaves of books were rubbed first with dry fingers, and then with wet ones, and the result microscopically examined. Few or no microbes were found on the dry fingers, but many on the wet ones..—*Ex.*

A CURE FOR DANDRUFF.—Dr. A. J. Harrison of Bristol, recommends the following salve for dandruff:

Caustic potash	8 grains.
Phenic acid	24 grains.
Lanolin,	
Cocoanut oil	āā ʒ jv.—M.

This preparation should be rubbed into the scalp morning and evening. Complete cure is usually effected in one to three months.—*I.a Progrès Med.*

Society Notes.

NEW YORK ACADEMY OF MEDICINE.

DISCUSSION.

DR. GEO. A. PEABODY: Our treatment and results in typhoid fever under all methods (save hydrotherapy) are disgraceful. I regret that Dr. Baruch should be able to name so few who use this valuable and scientific method of treating disease. One of the causes of the profession not availing itself of hydrotherapeutic measures is ignorance of the manner of applying them, of its technique and contra-indications. Until the past few years hydrotherapy was regarded as synonymous with the charlatan water cure, or its true physiological action misconstrued; so much so that, when I have recommended these measures, I have been advised to take care, else I would kill my patient. For many years the fear of the patient taking cold while suffering from fever has palled over the profession. This is wrong. It is almost impossible to give a patient with high fever a cold. Watch how he uncovers himself and thrashes around without the slightest untoward effect. As I have stated, our hospital statistics are shocking, mortality ranging from twenty to thirty per cent. Let us turn from this record to a brighter one. Brand, the great disciple of hydrotherapy, has collected 19,000 cases cases of typhus and abdominal typhus in which hydrotherapy was applied inefficiently, but still was used, with a mortality of but 7+ per cent. These cases were collected from all sources—army, navy, and civil life; while in 5,000 treated systematically by hydrotherapy only 3 per cent. died.

In the French and Austrian armies, where hydrotherapy is not systematically used, there is a mortality of 36+ per cent. in the former and 27+ per cent. in the latter. In the German army at large the mortality is 9 per cent. In the Second Army Corps, where the bath was used thoroughly, the death-rate was but 3 per cent. What a marvellous showing compared with our own statistics?

The objection has been made that the apparatus for the practice of hydrotherapy is cumbersome and expensive. This is false: its requirements are few and simple. An ordinary portable bath, a few linen sheets and blankets are all that are necessary, and should, with the exception of the portable bath, be of ready acquisition in every house and hospital. That it entails the necessity of skilled attendants is not a substantial reason, for the physician himself should personally attend to the procedure, and a very few minutes' instruction to an intelligent orderly or nurse, or even to an untrained but intelligent friend, will suffice. So much for the objections offered; they are untenable, narrow-minded and prejudiced.

Personally I favor the full bath, at the temperature of 65° to 70° F. (68° is a good average), and at as frequent intervals as necessary to keep the patient's temperature at or below 102° F. It is a mistaken idea that in hydrotherapeutic measures we should be guided by set and fixed rules as to the frequency of the bath; it is not so with other methods of therapeu-

sis. Our indication should be the patient's temperature, and kept at the degree mentioned irrespective of time limits, and not by rigid adherence to regular intervals of time; allowed to run up to 104°, and then knocked down to 102° or below. Many cases come into our hospitals late in the disease, and when I did not consider it advisable or justifiable to give the cold bath, I have used the cold pack. Nine cases of typhoid treated by this method in Bellevue Hospital have done well; in fact, better—they are convalescent. The graduated bath I do not believe in; I do not regard it as effective.

The time-honored Kibbe cot I regard as too severe for general use, although, in one case, a woman in the last stages of the disease, with pulmonary œdema, whom the house staff regarded as moribund, was put on the cot and water poured over her. The effect was remarkable: she was stimulated, the lungs cleared up, and she did well after this.

Cold sponging I think ineffective and do not use. I do not see how we can hope for good when the surface of the body is cold and the internal temperature high, and do not use it under these circumstances.

The thanks of the Society and of the profession at large are due to Dr. Baruch, for his thorough, systematic, scientific, courageous and persistent advocation of this most valuable method of tretaing disease.

A. A. Smith: I fully concur with Dr. Peabody in his expression of thanks to Dr. Baruch. I have used hydrotherapy and shall continue to do so. I am a sincere believer in it. Dr. Flint, whom I have just succeeded at Bellevue Hospital, introduced the cold bath into his service in four cases of typhoid, and they all got well. Since my attendance I have had five cases, which, having a moderate temperature, did not receive the bath, and they got well. I have listened to Dr. Baruch's opinion with a great deal of interest, and have noted many points for future reference and practice. For his suggestions in the treatment of neurasthenia we are deeply indebted to Dr. Baruch; as also in regard to hysteria. I am skeptical, however, as regards the cures mentioned. I believe that hydrotherapy may aid in this disease, but am skeptical of its effecting a cure. We should thank Dr. Baruch for his strict detail—it is of great benefit; and the utility of many valuable papers is marred by the non-observance of this essential point.

I am rather a believer in the pack in preference to cold bathing, as I believe the pack is more efficient in relieving the nervous symptoms. I also believe that moderately warm water will reduce the temperature, as is so often evidenced by the popular warm bath at the beginning of the eruptive fevers of childhood.

Dr. Mary Putnam Jacobi read a very interesting report of a case of

TYPHOID FEVER IN A CHILD ÆT. NINE.

(which will be published in full in this journal). In the course of her remarks she succinctly and lucidly explained the position of Dr. Baruch in relation to the antifebrile and not antithermic use of hydrotherapy. Dr. Jacobi desired to know if Dr. Baruch would treat malignant cases with low temperature by hydrotherapy.

Dr. Geo. B. Fowler: I am surprised that the bath is not more generally used. I use it in pneumonia, typhoid, the eruptive diseases of children, and locally by ice compresses in diphtheria. I believe that, besides reducing the temperature, the patient is materially benefited by the changes produced by the stimulation, reaction and improvement of secretion. I have another feeling in this matter, and that is we should drink more water. Young and old, infants, all should have plenty of water to drink. Water is one of the main essentials to the welfare of the human being, and plenty of it. I join my predecessors in their thanks to Dr. Baruch.

The President: If it were not for the late hour, I would voice my opinion, but will add my congratulation with the others.

Dr. Baruch, in reply: Owing to the late hour, I shall be brief in my remarks. The various points, pro and con, have been ably answered by the participants in the discussion, so there is but little for me to add. Dr. Jacobi, who has made deep and extensive studies in hydrotherapy, has fully explained my position. I use this measure for its antifebrile, not antithermic effects. Dr. Smith's skepticism I regret, but the facts remain. Hysteric cases deemed incurable when first admitted at the Montefiore Home by our examining physician, Dr. Ettinger and the Medical Board, were certainly cured by hydrotherapy.

In reply to Dr. Putnam Jacobi, Dr. Baruch said that in the malignant form of typhoid, the cold affusion, while patient was seated in a semi-recumbent position in warm water, was an effective measure to arouse the nerve centers, to whose lack of tone was due the feeble condition of the patient. K. B. P.

Paris Letter.

TREATMENT OF CHLOROSIS BY RECTAL INJECTION OF DEFIBRINATED BLOOD.

CHLOROSIS is one of the most difficult forms of disease to treat; and although all doctors know that iron is, so to speak, the heroic remedy for use in such cases, everyone of them also knows that a large number of such patients have great difficulty in tolerating the use of iron, either on account of an especial susceptibility of their organism, or else on account of the irritating action it manifests too frequently on the stomach, and of the gastric disorders it gives rise to. As a result, it has for a long time been the endeavor of physicians to replace iron by something better in the treatment of anæmia and chlorosis. For it is not only the action of the drug on the stomach, but also the fact that it has a congesting action on all the internal organs; and it has been justly accused of causing hemorrhage in lungs that are already predisposed to it. Bunge said that iron is more readily assimilated in combination with an organic substance which takes the place of

an acid, and it seems only natural that blood should be thought of, as it contains iron in the form of an organic compound. In its natural state it has been found repugnant to patients and difficult to take, and various preparations of powders and dried extracts have been used; but Dr. Teissier, of Lyons, physician to Hotel Dieu hospital there, has found a method that seems to give more success. He simply makes use of the power of absorption belonging to the large intestine, and administers blood to chlorotic patients by enemata.

The process followed is simple: Take some bullock's blood and beat it, to defibrinate it, and then put it in a pint jar — which must be placed in a water bath until its temperature reaches 34° to 35° centigrade—then inject one hundred and twenty-five grammes (four ounces) by the rectal syringe, and try and have it retained as long as possible when injected. Give two of such enemata per day, continue for a week, then stopping a week for rest, and so on for one to two months. As a rule it is well tolerated; but if any colic occurs nothing is more easy than to put a few drops of laudanum in the injection. Dr. Teissier presented twelve cases in which a considerable improvement took place.

In a scientific point of view the action was shown, 1. By a notable augmentation of the elimination of phosphoric acid and urea. 2. By an elevation of the hemochromometic degree of the blood. 3. By an increase of the number of red globules in the blood; and finally by a considerable increase in bodily weight. The action was also shown by an increase in strength and a fall of the temperature, while the mucous membranes were rapidly colored to the normal. M. Teissier considers that this method gives back to the blood the essential elements it has lost—that is, iron, oxygen, and the salts of potassium and chlorides. Certainly chlorosis and anæmia have not as their sole cause a deficiency of iron in the blood, the other elements, by decreasing in quantity, no doubt give rise to anæmia, so that, to give blood is theoretically the best way to cure chlorosis, and the present therapeutical experiment is worthy of the attention of practising physicians.

THE RELATIVE POWER OF CERTAIN DRUGS RECOMMENDED FOR ASEPTIC TREATMENT.

This question is still discussed, and authors differ about the best substances to use. Prof. Petresco (of Bucharest) has just published a long and interesting series of experiments he has been making for some time back to see which are the best of such drugs, or rather, what is the antiseptic power of each of them. Everything that has been recommended he puts into practice, and now gives the results. He found that, given equal conditions, he had the greatest success in typhoid fever with sulphate of carbon and naphthol-beta; and in tuberculosis he got the best results with the following mixture:

℞.—Eucalyptol	20	grammes.
Ess. turpentine	20	"
Creosote	20	"
Iodoform	0. 50	"
Ether sulph.	5	"

Dissolve the iodoform in the ether, and mix.
Sig. Use, by inhalation, in from two to three days.

In certain cases he used, creosote 50 grammes to guaiacol 5 grammes, in the same way; and in a few, eucalyptol 50 grammes simply.

The duration of treatment in these cases was from sixty to ninety days, but some of them were continued for five to six months, and in a few of the cases the drug was given internally also. Thirty-four patients were experimented upon, and 6 are given as cured, 19 improved, while 5 died. In small-pox and measles Prof. Petresco used Van Swieten's solution of bi-chlor. mercury internally, and a sulphur pomade externally. All the patients were given a teaspoonful of the solution of mercury night and morning, while they were rubbed over the whole body with cold cream and sulphur, in the proportion of 10 per cent. of the last, used three times a day. Thirty-one cases of small-pox so treated gave only 2 deaths, and 327 cases of measles treated in the same way gave only 11 lost. It would seem as though modern progress was fast going back to the drugs of our grandfathers. The old sulphur ointments are now largely used in all sorts of troubles, and pure sulphur is given internally, or else the old sulphur and molasses or treacle is given. Calomel, too, has had a considerable boom. Dochman, and other German doctors, give it—they say with success—in phthisis. The method used consists in giving it in decreasing doses; the first day twelve pills, then ten, nine, eight; and then for two months give six pills for three days in each week. The following formulas are given. The first one is used when there is gastric trouble, the second when hæmoptysis, and the third when cough is present:

℞.—Calomel	60 centigrammes.
Pepsine	3 grms. 50 centigrms.
Tinct. opii	30 drops.
Ext. phyllandrium aquat. q. s.	

M.—For sixty pills.
Sig. Give two every two hours.

℞.—Calomel	.60 cent.
Pepsine	3 grms. .50 cent.
Ergotine	.10 centigrammes.
Powd. licorice q. s.	

M.—For sixty pills.
Sig. Same dose.

℞.—Calomel	60 grammes.
Pepsine	3 grms. 50 cent.
Ext. hyoscyam.	30 grammes.
Ext. phellandrium q. s.	

M.—For sixty pills.
Sig. As above.

It seems pretty certain that the empiric methods of our fathers or grandfathers were based on antisepsis, although they did not know it; they simply saw that certain practices did good, without knowing why. A late work by Prof. Anagnostakis, bearing the title, "The Antiseptic Method Among the Ancients," shows that the old Greeks used antiseptic methods twenty-two centuries ago. It was used by them with all the strictness of modern surgical practice, and we seem to have come back to a forgotten custom. The book describes drying up of wounds, which was nothing else but antisepsis, and the substances they called *siccatives* were antiseptic drugs. Besides the historical interest in these old practices,

it should be highly interesting to read over the old methods of practice, as often, in medicine, we only seem to begin over again old and forgotten methods. In these old and forgotten practices there are surely some valuable antiseptic or other successful methods and drugs that would be useful if sought for. We are too apt to look for something new, and we throw out the "pointer" to our young students that they may find some gold mines in the old works if they choose to look for them; they will get the credit for it. Many of the older forms of medication are not known to modern doctors, and they are now seen to be equal, if not superior, to modern so-called progress. Perhaps old time experience is more than equal to the present-day straining after new drugs which cannot be tested for years and do not deserve confidence until they are thoroughly tested by time and experimentation, while the old drugs are already to hand, tried and tested by years of experience.

HOT WATER ASEPSIS.

It is claimed that the antiseptic action of *very weak* solutions of corrosive sublimate is increased by heat, and that so used they are as good as strong solutions. This has an important meaning. M. Chas. Richet, the professor of physiology at the Paris Faculty of Medicine, made mention of this matter in 1885, when he showed at the *Société Biologie* that 5 centigrammes of hydrarg. bichloride in 100 grammes of urine would prevent putrefaction if it were kept up to 43° centigrade; but if allowed to remain at 20° centigrade, it would rapidly spoil. A solution of three per cent. of carbolic acid will allow the virus of gangrenous septicæmia to grow, but it will destroy it if the solution is heated up to 36° centigrade. Several of our Paris surgeons use plain hot water in surgical dressings and some are now trying *very weak* solutions and find them sufficient when properly heated. The method certainly presents an advantage that all see at once, that is, that there is but little, if any, danger of poisoning of the system in such doses, and all the talk of toxemia after obstetrical operations is avoided by simply using hot and weak solutions.

THE HYPODERMIC METHOD OF GIVING DRUGS

is increasing in use in Paris, and indeed has taken a rapid extension in all France. Quite a school has been formed by Dr. Roussel of physicians who use this method only. The doctor edits a new medical journal, which is called *La Médicine Hypodermique*, which is now in its second year. The number of drugs thus used is constantly increasing. Eucalyptol, 20 per cent. in volume, is used for phthisis; iodoform, one part to vaseline oil 100; also sparteine, in 5 per cent. solution, is a favorite in heart troubles, fever and insomnia; arsenic, mercury, camphor, in neuropathic cases; paraldehyde, in 20 per cent. solution, is claimed to cut off nervous pains at once, as well as hysterical attacks. Iron preparations are injected, salicylate of iron, 2 per cent., being used in all forms of anæmia, chlorosis, hæmatemesis and uterine hemorrhages. Carbolic acid solutions are injected for suppuration and organic putrid affections, and also into boils and carbuncles.

TREATMENT OF INFLAMMATIONS OF THE THROAT AND TONSILS BY THE INTERNAL ADMINISTRATION OF SALOL.

Dr. Gouguenheim, physician to the Lariboisiere Hospital, where he has the largest laryngological clinic in Paris, gives some twenty odd cases in which he has used the above form of treatment. Some of the patients had acute tonsillitis and sore throat with fever, pain and dysphagia, and some of them had suppuration of the tonsils; others had scarlatina as well; and all were treated by the internal administration of salol, in doses of three to four grammes a day, suspended in syrup (as the drug is insoluble). It has been used in rheumatism, but not with so much success as salicylate of soda; but it was, however, noticed that it relieved pain in those cases. Dr. Cappart, of Brussels, first used salol for phlegmonous tonsillitis, and was astonished at its rapid action in such cases. In Dr. Gouguenheim's cases the pain was relieved very quickly, and the fever and dysphagia from one to two days, while the cases were completely cured in from three to four days. The conclusion is that salol acts rapidly on all forms of sore throat, no matter what the cause. It calms the pain and dysphagia, stops the swelling and redness very quickly, causes a fall of temperature, and gradually diminishes the duration of such affections. The dose should be at least four grammes a day.

While speaking of throat affections, it may be well to mention the use made of antipyrin as a hæmostatic after the operation of tonsillotomy. It is used in a strong solution applied locally; after one tonsil is enucleated, it will allow of the other one being extracted at once, as it stops all bleeding. It is also useful in epistaxis and hæmorrhages from the uterus.

HAS THE PROGRESS OF MODERN SURGERY MADE WAR LESS FATAL IN WOUNDED PERSONS?

is an interesting question that has lately been studied by Dr. Noel, acknowledging the progress. Is it possible that the improved methods will permit a lower mortality in time of war? Shall we be able by asepsis to prevent the terrible hecatomb that has been seen in past wars? This is an important question, as Europe may at any moment be plunged into a great war; but it would only be when all the difficulties of the strict application of asepsis in war times have been met that the question will be fully answered. Already, however, some of the late little wars can partially answer the questions that arise. Prof. Nimier, of the Military School of Medicine, called *Val de Grace*, in Paris, gives the statistics of the French war in Tonkin (1883–1885). There were 2,043 gun-shot wounds which gave 199 deaths. All the various wounds are given at length in the different parts of the body; 87 head wounds gave 22 deaths, but 9 of these were killed at once; 67 were face wounds, 173 throat, 119 abdomen, 47 of these were not penetrating and 82 were; 18 of this last lot survived, and 54 in all died, but 38 of them expired on the first day, 18 or more than half remaining, were saved, although the only treatment used was immobility and opium. These last results are rather discouraging to the partisans of immediate laparo-

tomy. The conclusion of this study is that war surgery is quite a different matter from that of peace, and cannot be well compared. The patient is first of all under conditions of fatigue before and after his wound. The difficulty of strict antisepsis is immense in war times. Certain operations, such as abdominal laparotomy, can hardly ever be made. Nevertheless, the improvements made in surgery have increased the chances of life, particularly in cases of fracture, and the general mortality has diminished.

THOMAS LINN, M.D.

Book Reviews.

STUDENTS' AID SERIES, Volume IV. Obstetrics. By SAMUEL NALL, M.D. Gynæcology. By ALFRED S. GUBB. M.D. New York: G. P. Putnam's Sons, 1889. 218 pages.

This volume of the Students' Aid Series is an especially valuable one, embracing as it does two complete subjects. The greater part of the book is devoted to the subject of obstetrics, which is discussed in a concise and masterly manner by Dr. Nall. He takes as his headings the anatomy of the pelvis and generative organs, and the fœtal development, pregnancy with its symptoms, complications and diseases, morbid conditions of the fœtus, abortion, premature labor, the mechanism of labor, the accidents and complications of labor, dystocia in its various forms, obstetric operations, and the puerperal state and its diseases. The whole ground is thoroughly reviewed and many of the later suggestions incorporated in the book.

The remainder of the book is devoted to a study of the diseases of women. This fruitful field for investigation by those inclined is presented by the author in a most agreeable and taking form. The anatomy of the uterus and its appendages, menstruation and its various disorders, sterility, diseases of the ovaries, Fallopian tubes and broad ligaments, extra-uterine pregnancy, moles, pelvic cellulitis and hæmatocele, diseases and displacements of the uterus, coccygodynia, chlorosis, the use of gynæcological instruments, all are given a place in this little volume. We take pleasure in recommending the book as one of some merit.

THE MEDICAL SUMMARY, PHYSICIANS' CALL-BOOK AND LEDGER, COMBINED. Arranged by R. H. ANDREWS, editor and proprietor of The Medical Summary. Accommodates daily charges for four hundred families, each account for the entire year on a single page by itself. Has Obstetrical Record, Record of Deaths, Nurses' Addresses, Vaccination Engagements, Cash Received, General Memoranda, Pencil Tablet, etc. Leather binding; tinted edges; price, $1.50. Address, The Medical Summary, P. O. box 1217, Philadelphia, Pa.

This is a very neat and convenient-sized visiting list and ledger, combined. By means of it the physician can dispense with the larger account books, and have always before his eyes his entire financial relations with each of his patients. The arrangement of the pages does credit to the ingenuity of Dr. Andrews, while the strong binding and attractive appearance of the book will give it a special value in the eyes of a busy and æsthetic practitioner.

A MANUAL OF MINOR SURGERY AND BANDAGING, for the use of house-surgeons, dispensers, and junior practitioners, by CHRISTOPHER HEATH, F. R. C. S., Surgeon to University College Hospital, etc., London, England. Ninth edition. Illustrated. Pp. 261. P. Blakiston, Son & Co., Philadelphia, 1889.

This little manual still retains its hold upon the favor of the medical profession, and the issue of a ninth edition only goes to prove how strong that hold is. We cannot say more than has already been said in its name. Rarely are the pages of any medical work so thoroughly crammed with facts of practical significance and every day application. All the minor parts of surgery, usually the most important, since the success of an operation depends largely upon the after-treatment—are here completely and concisely described, and profusely illustrated. The formulæ near the end of the book are extremely useful. We congratulate the publishers upon their new edition of this admirable little book.

Pamphlets.

The Progress of the Medical Sciences in Our Own Times, Henry S. Stark, A.B., M.D., Ph.D. Reprint from the *New York Medical Journal*, for August 31, 1889.

Overstrain and Underpower of Brain. A cursory survey for lay readers especially of the inter-reaction of psychical demand and physical supply, by C. H. Hughes, M.D., St. Louis, Mo. Pp. 22. Reprint from *Alienist and Neurologist*, for October, 1889.

Reply to a French Review of Essay LII (Therapeutics Ought to Become a Science), by William Sharp, M.D., F.R.S. George Bell & Sons, London, 1889.

A Year's Experience with Apostoli's Method, with Reports of Cases, by A. Lapthorn Smith, B.A., M.D. Lectures on Gynæcology, Bishop's College, Montreal, etc. Reprint from *American Journal of Obstetrics*, for August, 1889.

The Medical Digest.

IN ALBUMINURIA.—A scruple of phosphate of soda and half a scruple of iodide of potassium in a quart of milk, forms an excellent daily drink, to be used "ad libitum."—*Pharmaceut. Era.*

CALOMEL AS A DIURETIC IN HEPATIC CIRRHOSIS. Heinrich Kohn (*Centralbl. f. d. ges. Therap.*, May, 1889), reports a case of this affection, which is of interest as an aid in determining the exact value of calomel as a diuretic. The patient had been treated with various diuretics without notable effect, and eventually needed aspiration, but was unwilling to undergo it. The administration of 0.2 gramme of calomel three times a day was then commenced, guarded by opium, and with a simultaneous employment of a mouth wash of chlorate of potash. Under this treatment, continued for three days, there developed great weakness and exhaustion which necessitated its discontinuance. In the meantime, however, there had been a very marked diuresis, and the ascites was almost entirely removed.—*Amer. Jour. of Med. Sciences.*

THE CURE OF BUNIONS BY PHENIC ACID.—Dr. Salemi, of Nice, uses the following method: The foot is washed with soap and water, after which the adjoining healthy parts are protected by a thick coat of elastic collodion. The acid is now melted and applied to the hardened surface by means of a pointed brush. After allowing it to dry for several minutes, the excess of acid remaining may be taken up with ordinary blotting paper. This application should be repeated every three or four days until a cure results.

—*Revue Médicale de Louvain.*

DEODORIZATION OF IODOFORM WITH TAR.—Ehrmann, of Vienna, was the first to notice that a pomade of iodoform to which tar had been added no longer possessed the odor of the former drug, and he has employed this pomade in the treatment of syphilitic ulcers. M. Négel, of Jassy, has also remarked this fact.

M. Konya has obtained, by mixing 10 parts of iodoform with 100 of tar, a paste, in which the odor of the tar alone was noticeable.

By the addition of only 5 per cent. a pulverized mixture is obtained which has no odor of iodoform.

—*Lyon Médical.*

COCAINE HALLUCINATIONS.—MM. Magnan and Saury report three cases of hallucination due to the cocaine habit. One patient was always scraping his tongue, and thought he was extracting from it little black worms; another made his skin raw in the endeavor to draw out cholera microbes; and a third, a physician, is perpetually looking for cocaine crystals under his skin. Two patients suffered from epileptic attacks, and a third one from cramps. It is important to notice that two of these patients were persons who had resorted to cocaine in the hope of being able to cure themselves thereby of the morphine habit, an expectation which had been disappointed. For more than a year they had daily injected from one to two grammes of cocaine under the skin, without, however, giving up the morphine injections, which were only reduced in quantity. The possibility of substituting cocainism in the endeavor to cure morphinomania is a danger, therefore, which must be carefully held in view.—*British Medical Journal.*

MATINAL DIARRHŒA.—(Dr. Chauvet.) We are occasionally consulted by patients who complain of having, each morning, one or two diarrhœal stools, without any other need for defecation being manifested during the remainder of the day. These stools are produced immediately after getting out of bed; at times, however, the necessity may be felt before arising, but it is important to remark that it is always as the result of some movement that the desire makes itself felt. This desire is imperative, but it is not painful; the evacuations may be completely liquid; they are abundant and often fetid. Their number is variable; one or two passages is the general rule; sometimes we have as many as four, rarely more; and almost always in about the same period of time.

The abdomen is not painful to the touch; the appetite is almost always preserved, sometimes even exaggerated; thirst is habitually intense, and we find the *clapotement* of the stomach characteristic of dilation of that organ. Notwithstanding all these ymptoms, which may present a certain apparents gravity, as a rule the general health remains in a very satisfactory condition, and the prognosis is relatively good, especially as treatment has much influence on the progress of the malady. Observations show in effect that particularly the nature of the aliments taken, and above all the quantity of drink, have here much importance. These patients digest badly vegetables, fruit and meats covered with sauce, such as stews, etc.; in addition, almost all absorb large quantities of liquids. It is therefore in this direction that we must direct our treatment. We must especially recommend the avoidance of all drinks between meals, and establish the rule that the total amount of liquid taken in the twenty-four hours shall not exceed from seven to eight hundred grammes. The diet shall consist exclusively of roast meats, or, if boiled, well done, vegetable soups, stewed fruits, but in small quantities.

The evening meal should be very light, and, if possible, drink at this repast should be completely suppressed, for at least several days.

In almost all these cases the observance of these rules will be sufficient to cause a disappearance of the diarrhœa. At the end of seven or eight days the patients have generally returned to their normal condition; but we may, if it is necessary, still further assist in different ways, such as dry friction of the skin, hydrotherapy, mustard plasters applied at night, alternately on the stomach and on the back. If the diarrhœa be fetid, we must administer naphthol associated with salicylate of bismuth or iodoform.

—*Revue de Thérapeutique.*

TREATMENT OF OBESITY.—Frequently the practising physician is called upon to treat obesity in women where this morbid condition constitutes a most tiresome infirmity, and is often a complication of most of the affections of the feminine sex. We advise a faithful trial of the method of Schwenninger and Oertel, which has given so many excellent results in Germany. The following are the indications which have been laid down by these savants:

1. Elevate the tone of the muscular force of the heart.
2. Maintain the normal composition of the blood.
3. Regulate the quantity of liquid in the economy.
4. Prevent the deposit of fat.

The above indications are observed by the following methods:

1. The cardiac muscle is increased in tone by the augmentation of physical exercise—for example, by ascending elevations. It is necessary to progress with caution; the exercise will be gradual and the amount of work proportionate to the resistance of the subject.

2. To maintain the normal composition of the blood it is necessary that the alimentation should be

principally albuminous; it will consist of the lean of beef, roast or boiled, veal, mutton, game and eggs.

We can add green vegetables, such as cabbage and spinach, but fat and hydrocarbons shall be given only in small doses—for example, the amount of bread should not exceed 120 to 180 grammes a day.

3. We should limit each day the quantity of drink —180 grammes of coffee, of tea, or milk; 360 grammes of wine; 240 to 480 grammes of water will complete the amount of liquid absorbed in the twenty-four hours. Beer is entirely forbidden. Then, again, transpiration is excited by energetic exercise as well as by baths and coverings.

4. Lastly, the deposit of fat is attacked by the practice of the above-mentioned principles of dietetics.

This, for example, is how we should proceed:

Morning.—The cup of tea or coffee, with a little milk, will represent a total of about 180 grammes, and about 90 grammes of bread.

Noon.—From 80 to 100 grammes of soup, 210 to 240 grammes of beef, roast or boiled, veal, game, salad or vegetable, a little fish if desired, but cooked without fat, 30 grammes of bread or farinaceous pudding (never more than 90 grammes), 90 to 180 grammes of fruit in season, for dessert. It is preferable not to drink at the repast, but in hot weather we can allow from 180 to 240 grammes of a light wine.

Afternoon.—The same quantity of tea or coffee as in the morning, with, as a maximum, 180 grammes of water and 30 grammes of bread as an exceptional concession.

Evening.—One or two boiled eggs, 30 grammes of bread, perhaps a little slice of cheese, salad, and fruits; 180 to 240 grammes of wine, with 120 to 150 grammes of water.—*Revue de Therapeutique.*

Obesity and Sterility.—Obesity, when it goes as far as polysarcia, has a great influence on generation. In man, its production prevents the development of the genital organs. Two patients, aged eight and thirteen years, presented an atrophy of the penis and testicles. In another, thirty years of age, these organs were similar to those of a child of eight years. There had never been any erection or emission of sperm.

After adult age, polysarcia occasions a very notable diminution of the sexual desires, which are only reproduced by emaciation.

In women, amenorrhœa and dysmenorrhœa result from an excess of fat. This fat accumulates in the abdomen and exerts compression which prevents the utero-ovarian functions; perhaps ovulation does not take place because of the want of nervous excitation.

The suspension of the menses for several months, accompanied by an increase in size of the abdomen, is often the cause of an erroneous idea of conception. Certain patients have even the sensations of the movement of a fœtus.

A loss of flesh causes a return of these organs to a normal state, the menses become regular, and as the functions of generation resume their course, fecundation becomes possible.

Massage of the abdominal parts, and also of the internal genital organs of the woman, is one of the best modes of treatment to cause loss of flesh, and consequently is also an efficacious treatment of sterility.—*Gazette de Gynécologie.*

Antipyrin Incompatibles.—A short time since M. Carles drew attention to the precipitate which is formed by mixing solutions of antipyrin and extract of cinchona. M. Olliver, who has been making further experiments, says (Bull. Com. June, p. 278), that all the active constituents are precipitated together, and that there remain in the liquid hardly perceptible traces of alkaloids or antipyrin. According to M. Carles, however, the precipitate is readily soluble in weak acids, so that it might dissolve in the gastric juice, and the mixture, though unsightly, might not be inert.

(While this mixture might be perfectly safe to dispense, might not the more poisonous alkaloids be precipitated by antipyrin, which, on separating, would be given in large enough doses to produce serious results?—A. B. S.)

Another apparent incompatibility has been recorded by M. Blainville, who, having occasion to mix 4 gm. of antipyrin and 5 gm. of chloral hydrate in 15 gm. of water, observed that the mixture assumed a milky appearance, and upon clearing deposited an oleaginous liquid. After decantation this liquid soon crystallized, and then no longer possessed the taste of antipyrin or chloral, but a flavor rather resembling that of coriander seeds. Attention is called to the inconvenience that may result from the prescribing of complex substances that may change their physiological action altogether, and it is recommended that as far as possible, when ordering them, simple formulæ in which only distilled water and a simple flavoring agent enter, should be adopted.

—*Am. Dr.*, 1888, p. 170.

Iodide of Potassium in Diseases of the Heart.—In a lengthy article addressed to the Académie de Médecine on this subject, Professor G. Sée arrives at the following conclusions:

The true medicament for the heart is the iodide of potassium. Far from being a depressant, as has been sustained, it is applicable, on the contrary, in valvular lesions or in myocardiacs with feeble pressure; it increases first the energy of the heart, and also the vascular pressure.

Then, again, in dilating the arterioles, it increases the blood to the part, and as a result the heart finds itself delivered from its resistance and recovers its contractile power. The iodide thus becomes a true heart tonic. And by the vaso-dilatation, which naturally extends to the coronary arteries, or feeders of the heart itself, the iodide, in doses of from two to three grammes, and not in the insignificant doses of half a gramme, renders a new service in promoting the movement of the blood, as well as the nutrition itself of the central organ of the circulation, notwithstanding what morbid condition may there exist.

It is stated (J. Mosse, *Lyon Med.*) that ten minims of tincture of iodine, taken in half a glass of water twice a day, will cause the disappearance of warts The doctor has tested the drug in ten cases, with success in all.

Antiseptic Properties in Human Saliva.—From a series of experiments with the saliva of human adults, Dr. Floradin has found that the sulpho-cyanide of potash, which is always present, has decided antiseptic properties. — *Prager Med. Woch.*, Aug. 21, 1889—*Jour. Amer. Med. Asso.*

Sterilized Lint.—M. Regnier renders lint sterile by heating it to a temperature of 120° C. (248° F.) M. Regnier has tested the antiseptic value of lint thus prepared in dressings applied after operations of various kinds, with good results. At the recent Surgical Congress he stated that he considered sterilized lint equal to antiseptic dressings.

—*British Medical Journal.*

Actinomycosis Hominis.—Dr. L. Ammentorp reports in the *Nordiskt Medicinskt Arkiv.*, No. 24, four cases of actinomycosis in men—two of the upper jaw, one of the lower jaw, and one of the lung. In this last case the patient had worn a tracheal canula for several years. The author regarded the case as one due to infection through the inspired air, a mode or transmission of the disease not hitherto recognized.

—*N. Y. Med Record.*

Chlorate of Potassium.—Dr. Coghill, in a paper read at the Ninth International Medical Congress, confirmed the results of Wöhler that chlorate of potassium is excreted in the urine unchanged and in the full amount ingested, and hence does not give off the oxygen to the tissues. Nevertheless, besides its local uses, he finds it of value in preventing abortion, in all cases of pulmonary insufficiency, as phthisis, chronic pneumonia, and bronchitis, in anæmia, chlorosis, and general malnutrition. In addition it has an antiseptic action in diseases of the genito-urinary tract where there is suppuration or purulent or phosphatic urine.—*British Medical Journal.*

Vaccination on the Leg.—A French practitioner, in the course of a large number of re-vaccinations, was struck with the fact that the operation was far more successful when performed on the leg than when the arm was selected. He has since availed himself of the opportunity of verifying his first impression, and last year, having to revaccinate 177 school children, he chose the left leg in 99 and the left arm in 78, and carefully compared the results obtained, dividing them into three groups according as the eruption was typical, doubtful, or absent. Of the 99 cases vaccinated on the leg, 23 were typical, 31 doubtful, and 45 unsuccessful, being equivalent to a percentage of 23.2 and 31.3, respectively. Of the 78 children vaccinated on the arm, the numbers were 11 typical, 25 doubtful, and 42 failures, equal to 14.1 and 32 per cent., respectively. The percentage of failures was 45.45 on the leg, as compared with 53.84 on the arm.—*Medical Press and Circular.*

Medical News and Miscellany.

An Ohio lady proposes to make illuminating gas from lima beans.

Antipyrin and lanolin have just been adopted as officinal in the Austrian "Pharmacopœia."

The new bactericide, sodium-dithio-salicylate ii, is the special foe of the staphylococcus aureus.

Dr. Baruch's article upon Hydrotherapeutics which was accidentally crowded out and which is discussed in the present issue will appear next week.

A lady residing near Smyrna, Del., lived for one year after receiving concussion, dislocation, and fracture of the spine.

A Scranton husband cured his wife of confirmed invalidism by kissing the servant girl in her presence. The wife now does all the housework with ease.

A French court has recently decided that physicians are bound to give in good faith their professional services when solicited by those who represent the law.

The *Patria*, of Buenos Ayres, affirms that there is now in Bolivia a surgeon, Luca Silva by name, whose age is not less than one hundred and twenty-nine years.

Dr. Gravenigo, of the University of Padua, has lately grafted the cornea of a chicken upon a human eye with the result of forming a very transparent, shining, convex cornea.

A Williamsport dentist had the lower part of his face nearly torn away by a tooth-pulling machine which he desired to test before purchasing. He prefers the primitive forceps.

Five young New York doctors, who have been "walking" the Vienna hospitals, were recently arrested and fined for disorderly behavior in the streets of that city.

According to the British *Medical Journal*, the death of Father Damien was caused by an attack of malarial fever, which his constitution, undermined by leprosy, was unable to resist.

Dr. Galatti, of the Poliklinik, Vienna, speaks in high favor of lipanin as a substitute for cod-liver oil. It has been used for some time, with the most happy results, at the Children's Hospital.

Owing to the common adulteration of drugs by unscrupulous pharmacists, and the sale of unhealthy food, especially canned goods, there is a great necessity for a board of drug and food inspectors.

Dr. Ephriam Cutter, of New York, is still in England demonstrating his microphotographs of healthy and diseased blood morphologies. At a recent demonstration were present the Medical Director General of the British Army, and the Lord Mayor of London. Later he went to Aldershot and demonstrated to the medical staff of the army, and was tendered an honorary dinner.

In Vienna, recently, a thief seized a bag from a boy in the street. The boy was the son of a hospital porter, and the bag contained a human head intended for examination. The thief, no doubt, had a surprise.

Under the laws of Bulgaria, if a patent medicine is warranted to cure a certain disease and fails to do it, the manufacturer can be prosecuted and sent to prison. No cures for consumption can be found in that country.

The New York Board of Health is experimenting with a disinfecting apparatus in which dry heat is employed for destroying disease germs, thus obviating the damaging consequences of the usual methods of disinfection.

Dr. Pinel, of Paris, has been able to hypnotise patients by means of the phonograph. The commands given by the instrument were promptly obeyed, and suggestions were as effectual as though they had been delivered by the mouth.

Twenty-five is the lowest age at which a pharmacist in France will be permitted to take his oath. The university authorities have received orders to confer no diploma (without which students are unable to establish themselves) until the proper age has been reached.

Dr. Jackson, of Pittsburg, has recently analyzed a number of samples of pickles and catsups, and found that salicylic acid is used to prevent fermentation; while sulphuric acid to increase acidity, mineral coloring matters, and other adulterations, constitute some of the wholesome ingredients of these popular delicacies.

At a recent meeting of the Contemporary Club, Prof. Fullerton delivered an address on Hypnotism, illustrated by experiments. Among other addresses which followed, Dr. Gould took strong ground against hypnotism, denouncing its practice as dangerous to morality, and as being comparatively useless excepting as an exemplary of a peculiar phenomenon.

An Anglo-American Vienna Medical Association has been formed for the purpose of furnishing information to English-speaking medical men coming to study in Vienna. The office will be at No. 12 Landesgerichts Strasse. Membership will be open to any British or American physician or medical student, on payment of an entrance fee of one gulden.

The stated meetings of the Academy of Natural Sciences, of Philadelphia, are held every Tuesday evening, at 8 o'clock. The following is the arrangement of the programme: On the first and second Tuesdays of January, March, May, July, September, and November will occur the sessions of the Botanical and Conchological Sections, respectively; on the same days of the other months, the Mineralogical, Geological, and Entomological Sections, respectively; on the third Tuesdays of all the months, the Biological and Microscopical Sections; on the last or fourth Tuesday, elections, and reports of Council.

The second Congress for Tuberculosis will be held in Paris during the latter part of July, 1890. Professor Villemin will act as president. The following questions are to be discussed: 1. The Identity of Human and Bovine Tuberculosis, Also That of Other Animals: 2. The Bacteriological and Morbid Associations of Tuberculosis; 3. The Isolation of Tuberculous Subjects; 4. The Agents Capable of Destroying Koch's Tubercle Bacillus, With a View to the Prophylaxis and Therapeusis of the Disease in Man

The Board of Health held a lively meeting. They started in by instructing the solicitor to have warrants issued for the arrest of Drs. Ridge and Jarret, for violating the ordinance in not reporting two malignant diphtheria cases until after the patients had died. A warrant was also ordered to be issued for the arrest of William Tyler for selling bad veal. It was also decided to begin proceedings against all persons who have slaughter houses within the city limits. Keep it up!

An investigation has been made by the British Medical Association as to the physical development and brain state of school children. A report on fourteen London schools, drawn up by Dr. Warner, Secretary to the Committee appointed by the Psychological Section of the Association, shows that 15 per cent. of the pupils were in some respect defective; and these cases are classed under the heads of nervousness, low nutrition, abnormalities of skull, mental dulness, and eye defects.

The Trustees of the Johns Hopkins Hospital have authorized the issue of a monthly publication to be known as the *Hospital Bulletin*. It will contain all matters of general interest in connection with the work of the Hospital. Nine numbers will be issued annually, the first number appearing November, 1889.

The subscription price will be one dollar a year, which may be sent to the Publication Agency of the Johns Hopkins University, Baltimore, Md. We will welcome this new journal to our exchange table.

The laying of the corner-stone for the Philadelphia Polyclinic and College for Graduates in Medicine is a gratifying assurance of new facilities for pushing the study of medical knowledge beyond the point of graduation. There was no need for a duplication of hospitals in Philadelphia; but the Polyclinic is a hospital only for the facilitation of its larger usefulness as a college dedicated to the higher teaching for which it was instituted. It is in no sense a competitor of the medical colleges now in existence; but a coadjutor, finishing the work they have begun, and affording opportunities for post-graduates and active practitioners to add to their experience and proficiency.

When the new college shall have been completed it will hardly be necessary to go out of the United States to obtain a thorough medical education. The Polyclinic will afford to physicians desiring to pursue special lines of study the precise advantages desired.

—*Times.*

A REMARKABLE and unusual case of homicide has just taken place in Warsaw, Russia. While a peasant was undergoing an operation, after being chloroformed, he suddenly sprang up from the operating bench, and, in a frenzy of rage and terror, mortally stabbed the doctor and a Sister of Mercy. The patient was then removed to another hospital, where the operation was successfully performed without the aid of chloroform. The authorities in Warsaw are now debating whether the man should be tried for the murder of the doctor and the nurse, both of whom have died from the effects of the wounds they received, which were inflicted by one of the surgical instruments belonging to the unfortunate physician.

MEDICO-LEGAL SOCIETY.—The regular quarterly meeting of the Philadelphia Medico-Legal Society was held October 29, with President Schoales in the chair. The following were received as members in good standing: Drs. J. Hoffman, Daniel Longaker, H. Beates, Jr., H. H. Boom, S. T. Haines and Robert McCanney.

The following nominations were made: President, Dr. W. F. Waugh; First Vice-president. Dr. Martin; Second Vice-president, Dr. W. Buckby; Recording Secretary, Dr. Horace K. Reeger; Corresponding Secretary, Dr. T. H. McBride; Treasurer, Dr. G. M. D. Peltz; Board of Censors, Drs. Connor, Hazel and Stewart; Librarian, Dr. Nash.

A discussion arose on the case of Dr. H. K. Reeger, the Recording Secretary of the Society, who was tried and acquitted on the 9th of October, of assault and battery. A committee was unanimously appointed to draw up a resolution expressing the entire confidence of the society in the accused, and congratulating him on his honorable acquittal by the jury.

DR. H. AUGUSTUS WILSON, speaking of co-education and its effects in the Polyclinic Hospital and College for Graduates in Medicine, said:

"Co-education has been a matter of careful consideration at that institute, where it has been in oparation during the past four years. In many of the departments women physicians hold clinical positions, and the fact that the annual announcement of the Women's Medical College refers its past graduates to the Polyclinic for the instruction and facilities which are alone found there, has been the means of having a large number of women physicians in attendance at all times. It has been thoroughly successful and never an inconvenience or an obstruction to the men physicians, nor, as far as I am aware, has it prevented men physicians from attendance."

"Do the patients object to women physicians?" was asked.

"To the contrary, the peculiar kindly nature of women have, in many instances, attracted patients, and clearly proven that they are of advantage instead of disadvantage in the clinical work. The women who take up courses of advanced study are mostly highly educated and determined to brave all dangers in the quest of knowledge. Their work in the classrooms has stimulated both the men physicians and professors, and been an incentive to renewed energy."

To Contributors and Correspondents.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, United States Army, from November 3, 1889, to November 16, 1889.

By direction of the Secretary of War, Major Robert M. O'Reilly, Surgeon, will, at the expiration of his present leave of absence, proceed to Fort Logan, Colorado, and report in person to the commanding officer of that post for duty. Par. 6, S. O. 256, A. G. O., November 2, 1889.

By direction of the Secretary of War, leave of absence for two months, on account of sickness, with permission to leave the Division of the Missouri, is granted Captain Junius F. Powell, Assistant-Surgeon. Par. 2, S. O. 258, A. G. O., Washington, November 5, 1889.

Leave of absence for one month, to take effect about the 29th instant, is granted Captain C. N. B. Macauley, Assistant-Surgeon. Par. 2, S. O. 166, Dept. Mo., Fort Leavenworth, Kans., November 8. 1889.

By direction of the Secretary of War, Captain Louis M. Maus, Assistant-Surgeon, having relinquished the leave of absence on surgeon's certificate of disability granted him in S. O. 249, October 25, 1889, from this office, will, upon being relieved from duty at Fort Porter, N. Y., as directed in S. O. 242, October 17, 1889, from this office, proceed without delay to Fort Stanton, N. M., and report in person to the commanding officer, Department of Arizona. Par. 8, S. O. 261, Headquarters of the Army, A. G. O., Washington, Nov. 8, 1889.

The following changes in the stations of medical officers serving in this Department are hereby made, viz:

CRAMPTON, L. W., Captain and Assistant-Surgeon. From Fort Lyon, Col., to Fort Sheridan, Ills.

CORBUSIER, W. H., Captain and Assistant-Surgeon. From Fort Hays, Kans., to Fort Lewis, Col.

IVES, F. J., First Lieutenant and Assistant-Surgeon. From Fort Lyon, Col., to Fort Sill, I. T.

Par. 3, S. O. 167, Hdqrs. Dept. of the Mo., Fort Leavenworth, Kans., November 9, 1889.

Leave of absence for one month is granted Captain R. W. Johnson, Assistant-Surgeon, to take effect on or about November 10 proximo. Par. 4, S. O. 110, Dept. of Arizona, Los Angeles, Cal., October 29, 1889.

MERRILL, JAMES C., Captain and Assistant-Surgeon, is relieved from duty at Frankford Arsenal, Penna, and ordered to duty at Fort Reno, Ind. Ty. Par. 6, S. O. 256. A. G. O., November 2, 1889.

BLACK, CHARLES S., Captain and Assistant-Surgeon, is relieved from duty at Fort Sidney, Nebraska, to take effect upon the expiration of his present leave of absence, and will report in person to the commanding officer, Fort Du Chesne, Utah. Par. 6, S. O. 256, A. G. O., Washington, Nov. 2, 1889.

IVES, F. J., First Lieutenant and Assistant-Surgeon, is granted two months' leave of absence. Par. 3, S. O. 256, A. G. O., November 2, 1889.

By direction of the Secretary of War, the following assignments of officers of Medical Department (recently appointed) are ordered:

WILLCOX, CHARLES, First Lieutenant and Assistant-Surgeon, will report to the commanding officer at Fort Columbia, N. Y., for duty at that station.

MCVAY, HARLAN E., First Lieutenant and Assistant-Surgeon, now at Fort Mackinac, Michigan, will report in person to commanding officer of that post for duty.

FRICK, EUCLID B., First Lieutenant and Assistant-Surgeon, will proceed from Philadelphia, Penn., to Fort Keogh, Montana, for duty at that station.

Clinical Lecture.

CHLORIDE OF AMMONIUM IN THE TREATMENT OF CHRONIC BRONCHITIS AND WINTER COUGH.[1]

By WILLIAM MURRELL, M.D., F.R.C.,
Fellow of the Medico-Chirurgical College of Philadelphia.
Lecturer on Materia Medica, Pharmacology and Therapeutics at the Westminster Hospital, London.

ROYAL COLLEGE OF PHYSICIANS 13 DEC 89 LIBRARY

The value of chloride of ammonium in the treatment of affections of the respiratory organs is very generally recognized. From time immemorial it has been given in the form of mixtures, often in combination with carbonate of ammonium, senega and other drugs. Its pungent, saline taste can be disguised by the addition of a little liquid extract of licorice, say half a drachm to the ounce. Compressed tablets of chloride of ammonium are useful in many catarrhal conditions of the fauces and pharynx, and are largely employed by singers and public speakers. When the action of the drug on the larynx, trachea or bronchial tubes is required, a different mode of administration must be resorted to, and the drug is then inhaled in the form of fumes or smoke developed by the combination of the vapors of hydrochloric acid and ammonia. Many forms of apparatus have been devised for generating nascent chloride of ammonium, and I agree with Dr. Kendal Franks, of Dublin, who recently published an interesting article on the subject, that by far the best is the Vereker chloride of ammonium inhaler. I have had one in constant use for the last three years, and find that it answers admirably. It consists essentially of three bottles with connecting tubes. In the first is placed hydrochloric acid, in the second a mixture of ammonia and water, whilst the third, which communicates with the other two by a three-way tube, acts as a wash-bottle and separates any trace of free acid or ammonia from the vapor. The whole apparatus is perfectly simple, and a quarter of an hour devoted to putting it into working order and regulating it will afford a supply of inhalations for many weeks to come. The only difficulty I have experienced has been in setting the vertical tubes which regulate the the amount of air passing through the acid and ammonia to slide up and down in the india rubber corks. But this is easily overcome. All you have to do is to push out the tubes, clean them carefully, and apply a drop of oil, when they work with the greatest ease.

I generally detach the India rubber tubing leading to the mouth-piece and substitute for it a piece three or four yards long. The advantage of this is that the patient is not obliged to bend over the apparatus, but can sit back in his chair, or stand up and take a good deep inspiration completely filling the chest. Some patients do not know how to breathe, but take little puffs, which are no good; but a few minutes instruction and a practical illustration or two usually sets this right. One man, I remember, and only one, who could not be made to breathe properly. After several futile attempts to teach him, I got out of patience and packed him off to a singing master to have lessons in the art of breathing. It was a lucky thing for him that I did so, for his professor discovered that he had a tenor voice of exceptional tone and quality. He took lessons, and after a couple years' instruction and

[1] Abstract of a lecture delivered at the Westminster Hospital, London, England.

hard work, developed into a "professional," and is making a large income. He now blows a "cloud" with the apparatus with the greatest ease. Patients sometimes complain that the fumes are acid, and that they cause choking. As a matter of fact, a little excess of acid rarely does any harm, whilst an excess of ammonia is very irritating. The method for avoiding an excess of ammonia is simple. Put into the wash-bottle a little tincture of litmus and a few drops of acetic acid. As long as the water is colored red, there is no fear of any uncombined ammonia coming over, as it is seized by the acetic acid. When the water turns blue a little more acetic acid must be added. In cases of catarrhal deafness the fumes are readily forced up the Eustachian tube by filling the chest and mouth, pinching the nose, and then swallowing. It is astonishing what good this method of treatment does. Sometimes I use the chloride ammonium fumes alone, but far more commonly I employ them as a vehicle for the administration of other remedies. For example, I want to give pure terebene in a case of winter cough. All I do is to put a few drops on a piece of absorbent cotton-wool and introduce the little pellet into the water of the wash-bottle. The fumes which come over are impregnated with the pure terebene, and are carried to the innermost recesses of the bronchial tubes. In the same way I give inhalations of oil of cubebs, oil of sandal wood, and various other volatile drugs which exert a beneficial action on the respiratory apparatus. I have cured in this way obstinate cases of bronchial catarrh, chronic bronchitis, post-nasal catarrh, and deafness resulting from the obstruction of the Eustachian tube.

For the last three years I have employed this chloride of ammonium inhaler in a large number of cases, and the results, I am glad to say, have been almost uniformly successful. I have used it with equal benefit both at the hospital and in private practice. At the hospital the patients come every day for ten days or a fortnight, and the inhalation is superintended by one of the clinical assistants. It is not a good plan to give the patient the apparatus right off. He must be carefully instructed in its use, or too often he makes some mistake and does himself more harm than good.

The following are rough jottings from some of the cases in my note book :

Case I.—G. H., a member of Parliament, has had a bad cold for three days. Constant sneezing and running from eyes. Dull, heavy and depressed, can't read, and can't think. Little cough, but not much. Pain across forehead, and disinclination for exertion. Has had a Turkish bath, and took two pills last night. Has been using some strong smelling salts his chemist gave him. Is anxious to get well, as he has to speak in the House one day this week. Given the chloride of ammonium inhaler with pure terebene, oil of cubebs, and oil of sandal wood, in the wash-bottle. Much pleased with it, and insists on using it for nearly half an hour. Says the smell of the sandal wood is strangely familiar to him—can't account for it. Comes next day, and again inhales for half an hour. Writes at end of week and says he is all right, and that he made a brilliant speech.

Case II.—M. B., a general, retired. Is deaf. Has been deaf for years. Was in the artillery. Says all gunners deaf, so that they never hear anything not good of themselves. Has strange noises in his ears. Dislikes any noise in a room, especially rattle of knives and forks at dinner. Prefers dining alone on this account. General condition very bad, partly from want of exercise. Has consulted all the specialists, and has had his ears examined with many strange instruments. Says that the advantage of consulting many doctors is that no two of them agree, and that you are not alarmed by what they tell you. Not much in favor of inhalers. Tried one once, but it blew up. Is introduced to the Vereker inhaler, and takes to it kindly. Chloride of ammonium used first alone, and then with pinol. Purchases one for himself, and at end of month writes to say it has done him much good.

Case III.—Mr. McC. A,, well-known architectural sculptor, has had cough in winter for many years. Travels about a good deal, and is often in damp, dusty places. Is very short of breath, especially on exertion. Is ordered syrup of tar, and takes several pints of it. Also has the chloride of ammonium inhaler, which he used pretty constantly for two years, sometimes alone and sometimes with pinol, pure terebene, cubebs, or sandal wood. Takes pure terebene or pinol when he is travelling. Derives much benefit from the treatment, but never really gets rid of the cough."

Case IV.—Mr. C. C., formerly a Common Councilman, but has retired from business. Has mitral regurgitation. Irregular action of heart much benefited by small doses of digitalis or strophanthus. Very subject to bronchitis, and has to take the greatest care of himself. Has tried many remedies, but likes none so well as the chloride of ammonium inhaler. Three or four visits generally set him all right again. Always flies to it on the outset of an attack. Says it is his sheet anchor. Has consulted me at intervals for eight years.

Case V.—Captain W., commander of an Australian liner, has been at sea all his life, and is subject to a cough. Has had plenty of medical advice from his surgeons. Has a collection of prescriptions of his own. Tries them on other people, and if they do well, takes them himself. Is always taking medicine. Chloride of ammonium inhaler eases cough and brings up phlegm. Will take one on his next voyage with a supply of pinol, pure terebene and cubebs. Will try it on the passengers. He is not heard of again.

Case VI.—Miss A. W., singer, contralto, often loses her voice, especially when she has an engagement. Chest and vocal cords healthy. Thinks symptoms partly due to nervousness. Voice uncertain and apt to give in the wrong place. Something wrong with an upper C. Uses the chloride of ammonium inhaler and takes phytolacca assiduously for a couple of days before singing. Maintains that it does her good. Impossible to contradict a lady ; so treatment continued.

A word about the duration of the inhalation. At first I was accustomed to order it to be used for about

ten minutes three times a day; but further experience demonstrated that much better results could be obtained by inhaling for half an hour or more three times a day. This is a point to which sufficient attention is not paid. To get the best possible results from the Vereker chloride of ammonium inhaler, a certain amount of experience in its use is necessary.

The following case, recently treated at the Westminster Hospital, shows the benefit to be derived from the chloride of ammonium inhaler, combined with cubebs, when the inhalations are given daily for half an hour or more.

CASE VII.—Thomas S., aged forty-two, cook in the House of Commons, has had a winter cough for the last five or six years, attributable, he says, partly to the heat of the kitchen, and partly to having to cater for members of such various shades of political opinion. The strain on his mind is very great, and he fears that, unless he improves, he will have to give up the profession. He drinks beer, the wines at the House not being quite up to his mark. His cough troubles him and keeps him awake at night, and there is a good deal of expectoration. His chest is emphysematous, and there is a good deal of rhonchus at both bases. On March 28 he was given an inhalation for half an hour with the Vereker chloride of ammonium inhaler, and this was repeated on the 29th, 30th and 31st, with benefit both to the cough and shortness of breath. On the 3d of April the inhalation was repeated, with the addition of a few drops of oil of cubebs on absorbent cotton-wool in the wash bottle. This was continued daily for half an hour until the 11th, when all the prominent symptoms had subsided, and he was discharged practically well.

CASE VIII.—Jane S., æt. thirty-seven, has had a cough, chiefly in the winter, for eight years. It is always worse when she is pregnant, a condition which occurs frequently. The cough is hard, she says, and it reminds her of a dog barking more than anything else. The attacks come on in paroxysms and last ten minutes or more, accompanied by copious expectoration. She is a charwoman by birth, but does a little laundry work as well, and that knocks her up more quickly than anything. The cough makes her short of breath, and she has great difficulty in getting up stairs. She was treated with the chloride of ammonium inhaler, a few drops of cubebs being placed on the cotton-wool in the wash bottle. The inhalation was given for half an hour daily, and in six days, aided by a little improvement in the weather, she was so much better that, at her request she was discharged. She was given enough aromatic syrup of tar to last a fortnight and was not seen again.

The following is a case of chronic bronchitis in a beer drinker treated with chloride of ammonium inhalations.

CASE IX. — Eliza W., aged thirty-two, a bookbinder, has had winter cough for twelve years. The cough is hard and dry at first, and then after a time gets looser, and there is a good deal of expectoration. It is a violent cough, and is usually worse the first thing in the morning. The patient is a large beer-drinker; she does not care for spirits; but at night, when work is over, she and some other girls get together and drink as long as the money lasts. On examination she is found to be emphysematous, and there is a good deal of rhonchus over both sides of the chest. She is very nervous and shaky, and has to be given some quinine and iron before the treatment for the bronchitis can be proceeded with. On the 9th, 10th, 11th, 12th, 13th, and 14th she has an inhalation, for half an hour each time. The cough improves, the expectoration diminishes, and she is discharged with a recommendation to abandon the beer-drinking orgies in favor of a lighter and more frivolous form of amusement.

Case of bronchitis in a child (reported by Mr. E. Lucas Hughes) treated by inhalations of chloride of ammonium and cubebs:

CASE X.—Alice W., aged ten, is stated, on the authority of her mother, to have had a very bad attack of bronchitis when fifteen months old. She has suffered more or less ever since from bronchitis, usually in a chronic form, with from time to time acute exacerbations. It is bad all the year round, but worse in the winter. It commences quite at the beginning of the winter, lasts through the winter and early spring, without much improvement till May. The child is fairly well for only three or four months in the year. The attacks of cough are always violent and prolonged. The mother says it is a hard cough, which shakes the room. Sometimes it ends in vomiting. There is a great deal of phlegm, but usually it comes up quite easily. It is sometimes yellow and sometimes white, and sometimes it is streaked with blood. The child is short of breath, and cannot join in games as other children do. She does not lose flesh and her appetite is fairly good; but she is weak and delicate, and sweats a great deal at night. The parents were always ill, more or less; the father died of bronchitis, and the mother looks as if she would follow in his footsteps. On examining the child, she is seen to be thin and ill nourished. The chest is emphysematous, and there is sibilant rhonchus all over, back and front, with bubbling rhonchus at the bases posteriorly. She had had cod liver oil and a good deal of tonic medicine, but without materially benefiting the cough.

On April 9 she had an inhalation of chloride of ammonium from the Vereker apparatus, a few drops of oil of cubebs being placed on the cotton wool in the wash bottle. She soon learnt to inhale well, taking the fumes right down into the chest. It was repeated the next day, and on the 11th the time was increased to half an hour. During the inhalation she expectorated usually from two to four ounces of thick yellow phlegm. On the 13th and 14th the half-hour inhalation was continued, and then, in consequence of bad weather, the treatment was temporarily suspended, the child being unable to come in the rain. On the 19th the treatment was resumed, and the inhalation was given for an hour, the result being the expectoration of five ounces of mucus. On the 20th the inhalation was given for three quarters of an hour, and on the 21st and 23d for an hour each time. The last inhalations were on the 25th and 26th, when the child had improved so much that her

further attendance was not necessary. She had been under treatment seventeen days, and had had eleven inhalations. The final note was: The patient has very greatly improved. For the last five days there has been no expectoration during the inhaling, and although the weather has been very unfavorable, the cough has practically left her.

The following is a successful case in an adult:

CASE XI.—Mary H., aged twenty-one, is engaged in mantle making, and works ten hours a day, and sometimes more. She has half an hour's walk to and from business, and as her boots are bad and her cloak worn and thin, she often gets wet and catches cold. Her earnings are small and she does not get too much to eat. She has had a cough ever since she was fourteen; bad all the year round and worse in the winter. She has spat blood several times, a pint or more at a time, but never enough to prevent her going to business if they were busy. She has never been weighed, not being able to afford expensive luxuries. She is short of breath; but as she has no stairs to go up, does not complain. She is extremely anæmic, and looks weak and ill. She has some consolidation at the right apex, but there is no crepitation; probably in consequence of her straitened circumstances. She was taken in charge by Mr. Hughes, who superintended the administration of the chloride of ammonium inhalation with cubebs for ten days. It eased the cough and shortness of breath, and she was grateful. She was given some iron and cod liver oil, which did her good. What she wanted was a good meal; but that was not in the hospital pharmacopœia.

In many cases of congestion of the nasal mucous membrane and post-nasal catarrh the inhalation of chloride of ammonium is useful.

The next is a case of congestion of the nasal mucous membrane treated with inhalations of chloride of ammonium.

CASE XII.—Edith H., aged thirteen. It is stated by the parents that for the last three years she has not spoken clearly, and it seemed as if her nose were stopped up. She has never had any illness, except measles when eighteen months old, and since then she has never closed her mouth properly. A year ago she became very deaf. She had a profuse discharge from the right ear, especially at night. It lasted over a month and then ceased; since that her hearing has improved. Her tonsils were supposed to be enlarged, and she was treated with a gargle of potassium chloride (a saturated solution) for some weeks with benefit. She was sent to a special hospital for diseases of the throat, and underwent several operations, a portion of the mucous membrane being removed it is said, but there was no improvement. She snores at night, and always sleeps with her mouth wide open. On examining the nose the mucous membrane was found to be greatly congested, and the apertures were almost completely closed posteriorly. She was given the chloride of ammonium inhaler for forty minutes daily. After six inhalations the nasal mucous membrane was found to be nearly normal in appearance, and she could breathe with much less difficulty. After the tenth inhalation she was still better, and slept with her mouth shut. The inhalation was now given twice a day; half-an-hour in the morning and an hour in the afternoon. At the expiration of fifteen days the child was much improved. Two months later she returned, and on examination it was found that the mucous membrane of the nose was again very much swollen. There was a return of the old symptoms; she slept with her mouth open, made a peculiar snoring noise in her sleep, and was deaf in both ears. The inhalations were resumed for an hour daily, pure terebene and pinol being added to the water in the wash-bottle. The improvement was marked, but the inhalations had to be continued for a month before it was felt safe to discharge her.

The following is a case of obstruction of the nostrils, due to swollen mucous membrane in a child:

CASE XIII.—George C., aged fourteen, has been deaf, and has had much difficulty in breathing through his nose for the last seven years. He had measles when about five, followed by scarlet fever, after which he had his tonsils removed. He was a seven months' child, and has always been delicate. He has been at a board school, and has made much progress, but his lessons have always been a difficulty to him. In the winter he has a cough, and unless fed up and taken care of gets so weak that he can hardly get about. The mucous membrane of both nostrils is swollen and inflamed, and the right membrana tympani is ruptured. On April 12, treatment was commenced with the chloride of ammonium inhaler, the patient on four consecutive days inhaling for half-an hour a day. The cough was relieved and there was less difficulty in breathing through the nostrils, the mucous membrane of which was less congested. From the 17th to the 21st the inhalation was given for an hour daily, and the improvement was much more marked. The cough ceased, the breathing was easier, and the patient slept well at night. The inhalations were then discontinued, and the patient was given iron and cod-liver oil. The improvement resulting from the inhalations was very noticeable.

The following case treated by Mr. Lucas Hughes illustrates the benefit which may be derived from prolonged inhalations of chloride of ammonium in children:

CASE XIV.—Minnie C., aged eight, has always been a delicate child. Had scarlet fever, followed by croup, bronchitis, and inflammation of the lungs. Has had a cough almost ever since, worse in winter, but practically continuous all the year round. She sleeps with her mouth open, and is deaf in both ears. She is very short of breath, and is incapable of much exertion. She sometimes has acute febrile attacks lasting for several weeks, during which her eyelids swell and she sneezes a great deal. On examining the chest it was found that there was sibilant rhonchus all over both sides. She was given the Vereker chloride of ammonium inhaler, and told to inhale for half an hour. The treatment was commenced on April 21, and on the 24th it was increased to an hour a day. On the 26th, there is a note that the cough has greatly improved, and that she sleeps better at nigh

The treatment was continued until May 10, when the cough had ceased, and on examination of the chest it was found that the morbid sounds in the chest had disappeared. Her mother stated that she was better than she had been for some years. No difficulty was experienced in teaching the child to inhale, and she seemed thoroughly to enjoy the operation.

The following case was also treated at the Hospital:

CASE XV.—Kate S., aged twenty-seven, married, has had a cough more or less ever since she was three years of age, but it has been much worse the last nine years, especially in winter. She has five or six paroxysms every day, each lasting for three or four minutes. The expectoration is very copious, is thick and yellow, and comes up easily. She has noticed streaks of blood from time to time. She is short of breath, and has some difficulty in getting about. She has no appetite, and has been losing flesh for over a year. The chest was carefully examined, but nothing was detected beyond slight emphysema. Mr. Hughes gave her an inhalation from the Vereker inhaler daily for an hour for eight days, and at the expiration of that time she had much improved, and the cough troubled her but little. She was given Kepler extract of malt and cod-liver oil for a fortnight, and was then discharged much better in every respect.

Original Articles.

THE CASE OF DR. BROWN-SÉQUARD.

BY JOHN V. SHOEMAKER, A.M., M.D.

IT might, perhaps, be deemed presumptuous of me to pretend to decide the case of Dr. Brown-Séquard, in face of the manifold adverse final judgments of the secular press; but it is at least permissible to me, as to any other person, to state the case in a light of fairness which has not heretofore been always attempted; to review, in a word, the facts, and their bearing in the case, to see if these warrant the general condemnation with which the man and his theory have been visited.

As a preliminary, it will be well to point out that the arraignment has been entirely too general, that a charge accompanied by specifications is necessary to fair trial, and that this procedure has not been observed in the course of the animadversions against Dr. Brown-Séquard. Upon what counts is he to be tried? Is he charged with being criminal, imbecile, or ridiculous? If he is imbecile or ridiculous, he cannot be criminal; and if he is criminal, he cannot be imbecile or ridiculous. But it is proper to do first what has not been done—to determine whether it is the man, or the theory, or both, that are on trial.

If, as the rational order would dictate, the theory is to be placed on trial first, before the man can be applauded or condemned, then it will soon be apparent that the theory has had but the faintest semblance of a trial. But, certainly, both theory and man cannot properly be on trial at the same time, and it is lamentable to be obliged to confess that, before the theory has been adequately tested, Dr. Brown-Séquard himself has been put on trial and condemned.

Another necessary preliminary, it should seem, to acting in the interests of justice, would be that intending judges of the case should know what his theory really is, or else they are seeking to try a suppositious case, not the case of Dr. Brown-Séquard. Scarcely had the announcement of his alleged discovery taken place, when many of the secular papers of the country, without hesitation, ascribed to him the statement that he had discovered the elixir of life, and many of them still continue to harp upon that false string. Hundreds of articles in the secular press have appeared with this misleading allegation, and to the shame of the medical profession, there were not wanting articles even in medical journals which proved conclusively that the writers had never read the statement of Dr. Brown-Séquard himself. False allegations with regard to his claim having been made, were then adhered to; and writers manifesting sublime ignorance of the facts, and influenced by reports of unfavorable results from the administration of his suggested hypodermic injections, then set to work to vilify him, and the pleasant names of charlatan, quack, empiric, or, as alternatives, imbecile, dotard, jackass, were more freely bestowed upon him than were any of the honors which he has received throughout a long career. And yet we pride and vaunt ourselves upon belonging to the Anglo-Saxon race, which claims above all races to be lovers of fair play.

The usage of allowing some weight to the previous good reputation of the accused has been entirely forgotten in this case. Yet, if any man should have had good standing before the court of American public opinion, Dr. Brown-Séquard stands on the same footing as that man. By birth, American on one side, and French on the other, he twice married in America, and has from first to last in his career, although for the most part passed in Paris, shown the liveliest interest in, and affection for this country. His reputation as a physiologist, the growth of life-long study, is among the first in that branch of science in the world. His standing in an American, or any other court of public opinion, ought, therefore, to be good. Any charge that could be substantiated against him could probably be based upon nothing more unworthy than what has emanated from the life which he has led as a devotee of science and a recluse for the sake of benefit to his kind. If it be true that much learning has made him mad, or that imbecility has overtaken him, let us examine for the existence of these facts in what he himself has lately said, for there is no truer test of the sanity of a man than in what he says. If he be not actually imbecile, but only degenerated into a silly old man, calculated to make himself ridiculous at any and every turn, then he, being half a Frenchman, will readily agree to be put on trial on the basis of the French aphorism, that to be ridiculous is worse than to be criminal. But before we put him on trial at all, on any count, it is indispensable first that it should be shown what he really does claim, and then whether or not his claim can be sustained.

Let us, then, to begin with, see what he actually does claim. As the notes which he sent to the London *Lancet* are a *résumé* of the remarks which he had originally made before the Société de Biologie, of Paris, there are probably no words, not even including those of the original remarks, which could convey so precisely as these his exact meaning.

He tells us, at the beginning of his discourse on his theory, that he had had a general conception of the subject as early as 1869. This, it will be observed, was long before the period when he could possibly have been charged with imbecility, or even with verging upon that condition. He tells us that, prompted by his thought-tendency, he had, in 1875, made some biological experiments pointing in the direction indicated. He remarks that the degree of success which he achieved in these was small, but was still sufficiently encouraging, as indicating a latent principle of life, to warrant him in pursuing his investigations through what seemed an easier path to success. Accordingly, aided by the generalizations which he as a biologist was able to make from an immense number of facts, he began to pursue this path wheresoever it might lead. At the basis of all his thought thenceforward lay the probability, accepted by his mind, that in the elements of the living vertebrate body, represented by the seminal and ovarian fluids, lay great potency for the individual life; and if so, he argued, they might, if transfused into another similar living organism, temporarily revitalize it.

If even one of the laity, let alone a medical man, will for a moment reflect how intimately associated are the general health of the organism and the vigorous condition of the generative organs, he will perceive at a glance that the idea of Dr. Brown-Séquard is not far-fetched. Every monthly nurse looks at once at the scrotum of the new-born male child, to ascertain the degree of vigor that the organism possesses. The genitalia of the moribund shrink and shrivel as the supreme moment approaches, and when it is reached, suffer almost instantaneous, total collapse. Let a medical man reflect for a moment, that if these are matters of common observation, they must have been among the least of the manifold sources of induction from which Dr. Brown-Séquard conceived the theory that the seminal and ovarian fluids must possess great vitalizing potency. He contemplates the sluggish condition of the eunuch and the condition of continent men not eunuchs; the condition of men in youth, their changed condition with the advance of age; and he finds, lying side by side with all functional decline, that the most marked to the individual, although least manifest to the world, is that of the sexual attributes.

Under the circumstances, it is not utterly astonishing that he should have been led to think that, as among all evidences of senility in men and women, the loss or diminution in the generation of the fluids which respectively belong to the two sexes is the weightiest as to the physical degeneration of the organism, the diminution of the fluids might be regarded as one of the *causes* of the degeneration of the organism. This, however, as we regard it, is the weak point in his conception—the idea that, at all periods of life, whether in youth or age, the organism is renovated by resorption of these fluids. This makes an effect in turn a cause within the organism itself, which, if acting, would make of the alternating cause and effect a condition analogous to perpetual motion. This violates a principle of nature. We can readily conceive the proposition that fluids taken from one organism and transfused into another may possibly have a renovating effect on the recipient organism, but not that an isolated, independent organism can to any degree go on revitalizing itself. That the waning powers of the system should, as a part of vital decadence, fail to produce in quantity or quality the seminal or ovarian fluids, as originally secreted by the organism, is a matter of common observation. That these fluids should, at any time of life, as a consequence of their production in any kind or degree, make a store of force upon which the general organism draws, is not in accordance with the lines of scientific thought. The proposition, however, that their potency, as being physically representative of vital force and its propagation, may be effective in temporary revitalization of organisms other than those from which the fluids were extracted, is perfectly comprehensible, and strictly in consonance with the lines of scientific thought.

But this discussion is only incidental to the main purpose of a review of the treatment to which Dr. Brown-Séquard has been subjected. It will be seen that, whether partially or wholly wrong, he has merely stated a theory of his, and that in so doing, he has affirmed nothing dogmatically, but has given his reasons at every step for his conclusions. There is something to be said for him in addition to all this, that he does not ask to have his views received upon his mere statement. On the contrary, he does not accept them himself without proceeding to the test of experiment upon himself, and through Dr. Variot, a distinguished medical friend of his, upon several persons of advanced age. And with relation to these tests he speaks with all the qualifications and due reserves becoming a scientific man. By these experiments in sum he is confirmed in his conclusions, but he does not rest satisfied there. He, as a scientific man, knows that a few experiments cannot establish the truth of such an hypothesis as his, and so he appeals to the medical world to repeat his experiments with the testicular fluid to the end that, if what he surmises be found true, the discovery would be for the benefit of humanity. His marked carefulness and modesty of statement, coupled with perfect clearness, cannot but strike anyone who has read his original declarations. Let us refer to a portion of his own language in proof of what is here said. He concludes the remarks sent to the London *Lancet*, as follows:

"I believe that, after the results of Dr. Variot's trials, it is hardly possible to explain the effects I have observed on myself otherwise than by admitting that the liquid injected possesses the power of increasing the strength of many parts of the human organism. I need hardly say that those effects cannot have been due to structural changes, and that

they resulted only from nutritive modifications, perhaps in a very great measure from purely dynamical influences exerted by some of the principles contained in the injected fluid.

"I have at present no fact to mention which might serve to solve the question, whether it would be possible or not to change structurally muscles, nerves, and the nervous centers, by making, during a good many months' frequent injections of the fluid I have used. As I stated at the Paris Biological Society, I have always feared, and I still fear, that the special nutritive actions which bring on certain changes in man and animals, from the primary embryonal state till death by old age, are absolutely fatal and irreversible. But in the same way that we see muscles which have, from disease, undergone considerable structural alterations, regain sometimes their normal organization, we may, I believe, see also some structural changes not essentially allied with old age, although accompanying it, disappear to such a degree as to allow tissues to recover the power they possessed at a much less advanced age.

"Whatever may be thought of these speculations, the results I have obtained by experiments on myself, and those which have been observed by Dr. Variot on three old men, show that this important subject should be further investigated experimentally."

Would any of the gentlemen of the press who have so lavishly poured ridicule on Dr. Brown-Séquard during the last few weeks, have stated more modestly than he the provisional conclusions which he has reached? What, even if he prove to be entirely in the wrong? Is only the finding of truth noble? Is not the search, the sacrifice for truth, the noble part of effort, and the finding of truth only the crown of glory? But often even the finding of it does not obtain any but the martyr's crown. We can demand no more of Dr. Brown-Séquard, or of any other man who has the right to speak on subjects deeply studied, than that he shall frankly speak the truth that seems to himself to be in him. It is a great wrong for those to perpetrate who would applaud if truth were found, and they benefited, but have no mercy on the earnest but unfortunate seeker for it.

But how can we be certain that Dr. Brown-Séquard has not found the truth? He does not claim, despite what the papers say, that he has discovered, what amounts to the same thing, the elixir of youth or of life. His claims are strictly bounded by the most precise language, and amount in sum to saying, "Having conceived, from previous study and observation, that I could utilize to advantage in the human organism a fluid which would temporarily revitalize it, I have tried, or have had tried, and as I think successfully, a few experiments tending towards the determination of the question. I do not claim that these few experiments are conclusive as to covering all human idiosyncrasy, but such as they are, I commit the knowledge of them, with the formula which I have used, to the experimental tests of the medical world, with the hope that they will be confirmed."

How has the medical world at large in this country, not all the medical world here, acted in this regard? Perhaps Dr. Brown-Séquard would have been more discreet if he had incidentally communicated the fact that he has one of the best laboratories in Paris, that all his life he has been accustomed to trying the most delicate experiments and had said that he must caution his professional brethren who are not possessed of excellent appliances, and are not adepts in manipulation, to be wary in their procedures. He did not do so; he was too modest a man for that, and he took too much for granted. He took it for granted, for instance, that no doctor would walk down to a market-house, and upon the interested statement of a butcher that his lamb-fry was rather fresher than even when possessed by the original owner of it, proceed without any antiseptic precautions to make a concoction with a little micro-organic water, and then inject a fluid centimeter of it into a patient desirous of revitalization. An experiment tried without all the conditions imposed is an experiment, but not the experiment prescribed. A case once occurred where a man was informed that, if he would build a flue alongside of his water-closets in the basement of his house, a fire near the bottom of it would draw off through the flue all the smell from the closets. But, as an improvement upon his instructions, he built the fire-place in such fashion that heat sent the effluvia through the house. Dr. Brown-Séquard's theory has not been fairly put on trial, and yet, as has been said, he has been vilified to a degree that would have been warranted only, if, instead of having honest intentions, he had been guilty of a fraud. One of the very few fair examinations of the subject which has been made, is found in the paper of Dr. Henry P. Loomis, of New York, the conclusions which he has reached being derived from his own careful experiments. A passage from this paper will evidence how carefully he has worked. It reads as follows:

"I can see no reason to anticipate danger of septicæmia from the use of the fluid prepared under proper antiseptic precautions, provided the material used be absolutely fresh and free from all traces of disease. My attention was called to the necessity for the closest scrutiny in this last particular, by having discovered, in specimens taken from an apparently healthy ram, a solitary tubercle in which were demonstrated tubercle bacilli. In none of the cases have I seen any bad results, and only in a few has there been a moderate amount of pain at the point of injection, lasting from six to eight hours.

"I can explain the singular nervous affection apparent in certain of the cases, only on the theory that upon the nerve-centers the mixture exerts some powerful, but, as yet, unexplained influence, which, even if its use be eventually proved beneficial in some cases, must render its employment in others a matter of caution. It is far from safe to say, and proceed upon, the belief that if it does no good it can do no harm.

"I seem to see in almost all the cases of *old men* subjected to the experiment, an increase in strength and vitality, which certainly persists for several days. I have noticed nothing in the least resembling the secondary depression which so commonly follows the use of ordinary stimulants.

"When used in cases of actual disease, no modification of pathological conditions or processes has been recognizable.

"I therefore conclude that the injection of this testicular mixture does, as claimed, produce nutritive modification in the tissues of elderly men, due probably to the stimulation of the nerve-centers.

"As far as my own experiments are concerned, sufficient time has not elapsed to justify an affirmation or denial of the correctness of Dr. Brown-Séquard's second conclusion.

"There is in the theory sufficient ground for further experimentation."

These views have about them the true scientific ring. Deny nothing, unless it offends against some cardinal principle accepted by scientific men. If a man says that he has discovered the wherewithal to neutralize the attraction of gravitation, it is not even incumbent upon one to call his attention to the phenomenon of his walking, to the evidence against him in the sun, moon and stars. It suffices speechlessly to walk away. So of other claims to discovery that might be adduced. But barring this conflict with universally accepted general law, a scientific man is bound to try and test, to enable him to hold fast that which is good, and to reject that which is false. Only upon the terms of assuming nothing positively, until it has been weighed in the balance, can he possibly be sure of reaching any truth. It is evident, therefore, that Dr. Brown-Séquard cannot be placed on trial even for incompetency until what he has claimed shall have been given the consideration which it has not yet received. The scape-goat did not pass away with the Jewish dispensation. Men like, as of old, to visit their own sins of omission and commission on the heads of others. The profound silence with which the announcement of Dr. Brown-Séquard was at first received, and then the hopeful murmurs that arose, and then the eager advance of worshippers to the shrine of youth, presided over by a portion of the medical priesthood, is the best possible evidence of the existence of a latent, unexpressed, general wish always to be young. The strength of the reaction of sentiment proves the power of the original credulity. But there are fluctuations in the minds of men that rise and fall, although not so regularly as those of ocean. Let us hope, therefore, that upon a more reasonable wave of public sentiment than the second, crediting not that youth can be regained, but that something beneficial may still exist in the theory of Dr. Brown-Séquard, working for revitalization in the human race, writers on the subject, for the sake of justice if for nothing else, will carefully guard themselves against denouncing either the theory or the man as false, until they are a little more certain than they generally are at present of the facts.

A DEATH has occurred in St. Agnes's Hospital from spurious hydrophobia. The deceased, bitten by a dog nine months ago, was frightened by ill-advised friends into the belief that he had the rabies, and fell a victim to his hallucination and the absence of M. Pasteur.

ENUMERATION OF THE BLOOD CORPUSCLES

By SAMUEL WOLFE, M.D.,
SKIPPACK, PA.

FOR the purpose of comparing the number of corpuscles, or rather of ascertaining their divergence from what is assumed as a normal ratio, in different individuals, such an apparatus as Gowers' Hæmacytometer is indispensable. It is therefore a legitimate portion of the outfit of the physician and surgeon, or at any rate of the pathologist. But for purely physiological purposes, we may resort to a method of computation based on the proportionate weight of the corpuscles, as a component of the blood, and of the individual size of a corpuscle. It is interesting to note the close correspondence in the result, to that obtained by the hæmacytometer. If we take the minimum size of a red corpuscle, 1-4000 inch in greater diameter, the percentage of weight of the red corpuscles to the entire blood, 45 per cent., the specific gravity of the plasma 1025, and the specific gravity of the red corpuscles 1088, we are ready for the demonstration. In one millimetre, or $\frac{1}{25}$ of an inch, we could arrange 160 corpuscles in a row, 160x160 in a square, and 160x160x160 in a cube. This assumes the corpuscles to be spherical, but since they are only $\frac{1}{12000}$ in. in thickness, or $\frac{1}{3}$ as thick as wide, a packed cube (1 cu. m.m.) would contain 160x160x160x3 = 12,288,000. The percentage of weight is 45. The percentage of space occupied would be 45 per cent. if the specific gravity of corpuscles and plasma were the same. Since this is not the case, determine the percentage of space by the proportion 1088 : 1025 : : 45 : 42.4 nearly. 12,288,000-x.424=5,432,312, as the number of corpuscles in a cubic millimetre.

When it is remembered that the minimum sized red corpuscle was taken as the standard, we may be allowed to assume that the number is somewhat smaller, and thus bring it in close correspondence to the number given as the physiological standard or, 5,000,000.

RUPTURE OF THE UTERUS.—1. In cases of rupture of the uterus, with the head presenting, delivery by forceps should be attempted, but should be abandoned if not found easily practicable. Turning should not be undertaken, but the case should be at once recognized as one for either the Cæsarean or Porro operation.

2. In cases of ascertained incomplete rupture, treatment should be by antiseptic irrigations and rest.

3. All cases of ascertained complete rupture should be submitted to abdominal section so soon as the condition of the patient with reference to shock will admit, for the following purposes, viz.: (1) to explore the abdomen, (2) to remove all foreign bodies, (3) to cleanse the peritoneum, (4) to close the rent if the labor has been short, and the uterus not seriously damaged, and (5) to remove the uterus if the labor has been long, and the uterus seriously damaged.—*Dr. Charles A. L. Reed, in New York Medical Journal.*

Hydrotherapeutics.

A PLEA FOR THE PRACTICAL UTILIZATION OF HYDROTHERAPY.[1]

By SIMON BARUCH, M.D.,
Attending Physician New York Juvenile Asylum and Manhattan General Hospital.

ALTHOUGH it is the first-born offspring of therapeutics, water has experienced many vicissitudes in its struggle for the permanent position which it must surely attain as a remedial measure.

It shall be my aim this evening to appeal to you in behalf of its more general utilization, and my plea shall be based upon historical, physiological, and clinical grounds, which, I trust, through you, may lead the profession here to the realization that this most gifted child of medicine has been maltreated and neglected, and its power for good impaired by an imperfect appreciation of its merits. As I have said on a previous occasion from this platform, I shall not attempt to furnish you an exposition of the hydropathic, or water-cure system—that system whose beneficent results are, according to its enthusiastic advocates, destined to revolutionize medicine and to inaugurate the millenium of therapeutics, combining the utmost simplicity with the most marvelous efficacy. On the contrary, it is my purpose to divorce the remedial use of water from its empirical union with hydropathy, by urging its simplified utilization by the general practitioner in his every-day rounds.

The history of water as a remedy is, as I have elsewhere said, replete with interest, and affords the clearest demonstration of the instability of therapeutic propositions, and the influence of prevailing thought upon the latter.

Its literature is among the most extensive of any remedy. The Surgeon General's library contains titles of five hundred works and essays upon this subject, and Plohn prints the titles of nineteen hundred and twenty-five essays in his account of the Literature of Hydrotherapeutics, up to 1882.

Despite this vast accumulation of historical, experimental, and clinical material, the modern works on therapeutics discuss the subject in a few beggarly lines or pages; preferring to devote their columns to the problematical mode of action and effect of remedies which have not received one tithe of the investigation and practical demonstration.

Vienna, Paris, Bordeaux, and Lyons are to-day the only medical centers where hydrotherapy is systematically practised in the regular hospitals. In the former two cities it is taught also by able professors.

Hence, institutions abound in these countries, where water is applied with more or less precision to the treatment of disease.

A rapid survey of the history of water as a remedy will sustain me, I trust, in the view with which I desire to imbue you—that no remedy has passed so many conflicts with credit, and that despite professional and lay prejudice, it stands to-day unscathed, and challenges assault, secure in its physiological and clinical panoply.

If the history of medicine were the subject of a few lectures in the medical course, much unnecessary labor and groping in darkness would be spared the student and future investigator, and much good would acrue to his future patients. It is singular that while other professions and trades regard the study of the history of their subject as an important element of their education, the physician alone permits this vast field to stand untilled. To the restless medical mind, ever alert for new discoveries, the past seems to present no charm; and yet, no subject can be logically and scientifically discussed without a knowledge of previous achievements in its time. The history of the world, says Göthe, is the forum of the world. It alone presents to us a portrayal of truth, and guards us against error. The study of the history of medicine has always interested me, and in no direction has it afforded me more substantial grounds for positive opinion than in therapeutics.

The works of Hippocrates, the father of systematic medicine, illustrate how a master mind may grasp facts and make deductions which may stand the test of time. Appearing upon the stage of action at a time when the greatest confusion had been brought into the treatment of disease by priests, philosophers, and physicians, the great genius brought order out of chaos into every branch of medicine, and endeavored to endow with true scientific dignity the empirical knowledge of the day. In his tract on the Use of Fluids, he lays down rules for the treatment of acute and chronic diseases *by water* which are to-day followed by empirics as well as physicians. After his death opposing doctrines prevailed. Among the Greek physicians and philosophers who, during the rise of Roman greatness, emigrated from their native land to seek fame and fortune among the world-conquering people, was *Asclepiades*, of Prusa. Leaving Alexandria, and Athens, one hundred years before Christ, he entered Rome under Marius and Sulla.

Though belonging to a despised class, he became the bosom friend of Cicero and won for himself eminence, respect, and professional reputation because of his great medical talents, his marvelous cures, and especially on account of his genial and sympathetic nature. It was his chief aim to cure "cito, tuto et jucunde." Hence he cast aside all active medication. Although he practised bleeding, he did so cautiously, and he depended chiefly upon diet, rubbing, exercise, and *baths*. I have frequently remarked, in the study of this subject, that the same men whose judicial medical thought elevated them so far beyond their contemporaries as to resist the prevalent practice of excessive venesection and active medication, exhibiting a regard for the conservative tendencies of nature; the men who, in those dark days of medical history, approached most nearly the spirit which governs the therapeusis of the present enlightened era, these were the men who were invariably pronounced advocates of water as a remedy.

Asclepiades, the philosophical founder of the school, from which sprang Thernison, Antonius

[1]Read before the New York Academy of Medicine, November 7, 1889.

Musa, Cornelius Celsus, Cœlius Aurelianus, was so warm an advocate of baths and douches that he was dubbed *Psychrolutes*. Through him hydrotherapy was popularized in Rome. A member of his school it was, Antonius Musa, who maintained the aim of his noble master, to rescue his calling from the disrespect with which it was regarded. To him the Emperor Augustus owed restoration to health by a vigorous cold water treatment.

Suetonius tells us that the grateful Cæsar bestowed, not alone upon Musa, but upon the entire medical profession, the privilege of citizenship, besides erecting to him a statue next to Æsculapius. Horace, too, was his patient. His First Book, Epistle VI (Smart's translation) tells us: "Antonius Musa pronounces Baiæ to be of no use to me, yet makes me obnoxious to the place, where I bathed in cold water, even in the midst of the frost, by his prescription."

Cornelius Celsus, the learned Roman, called Lationorum Hippocrates, Medicinus Cicero, the bosom friend of Ovid and companion of Fabius Maximus, prescribed water freely in acute and chronic diseases. His opinions on the prevalent bloodletting mania of his day mark him as an eclectic of the highest type.

The same may be said of Cœlius Aurelianus, who was the originator of the abdominal compress of wet sponge for hypochondriacs. Galen, too, was an able but judicious advocate of cold water baths, and advised cold affusions upon the head while the body was immersed in warm water.

In the dark days of medicine which followed the death of Galen, when all branches of human knowledge suffered from the ignorance, witchcraft, and fraud arising from the barbarism of migratory peoples; from the destruction of the Alexandrian library and school; from the demolition of the Roman empire, the plundering of the Saracens and the conquest of Spain, science and art lay prostrate. At this time Alexander of Trolles and Paulus Ægineta appeared like meteors upon the medical horizon. The former refused to rely upon any system of medicine, but insisted with true philosophical spirit, which would do credit to him to-day, that the physician must depend in each single case upon the age, constitution, natural powers and mode of life of the patient, as well as upon the climate and all allied conditions and effects of nature. He furnished directions for bathing and rubbing in many diseases, and a special diet in gout. Paulus Ægineta, who is regarded as the greatest physician of the seventh and eighth centuries, was an enthusiastic advocate of water, and he it was who first advised the cold douche for anuria.

The next prominent figure in the history of hydrotherapy is Savonarola, the grandfather of the unhappy famous professor of Ferrara. He cured the Marquis D'Este by cold affusions, and recommended them in fever, dysentery and leucorrhœa.

Since no history seems to be complete without the Chinese, I may mention that Julien (Compt. Rend. 1849) tells us that in the annals of the dynasty of Hâs the biography of Hoa, a celebrated physician, is written. Hoa used hydrotherapy by sweating and cold water. In the case of a woman suffering from rheumatism he ordered one hundred affusions. Although the woman thought herself dying after the seventeenth, he persevered until the hundredth had been received; then wrapped the patient in a warm bed for a reaction.

In the seventeenth century Herman Van der Heyden regarded water as a panacea, reporting three hundred and sixty cases of malignant dysentery cured by its use. Passing over lesser events, we come to an epoch in hydrotherapy created by Floyer, the Englishman, whose book, published in 1697, passed through six editions, and was translated into German forty years later. Although he was an educated physician, he may be termed the first exclusive hydropath. He energetically propagated his views by his writings, making many converts at home and abroad. This learned enthusiast was succeeded in the advocacy of hydrotherapy by Frederick Hoffman, the most illustrious physician of Europe at the time. He held a professional chair, and commanding great respect, found many followers. His doctrines were imported into Italy, and thence found their way to France, and again back to England, where Floyer had prepared the way.

Theden, the surgeon of Frederick the Great, was the first to use water in smallpox, malignant fever, rheumatism and inflammation of the joints. He improved the shower bath.

In 1743, a Silesian physician, Johann Sigmund Hahn, and his son, established the principles of modern hydrotherapy in Germany, applying it in acute and chronic disease, especially in smallpox and the other exanthemata. Hence the same country which later produced the first great empiric, Preissnitz, may be credited also with the first great hydrotherapist. During the prevalence of the pest in Moscow in 1771 cold water was very successfully used.

Among the few historical facts which are familiar to most physicians, the exploits of Wright and Currie in the treatment of acute fevers may be mentioned. Currie's work was translated into several languages, and his practice was introduced into the Vienna hospitals by Joseph Frank.

To mention Hufeland, the enthusiastic yet judicious advocate of hydrotherapy, is to give the imprint of true medical wisdom to it and to indicate its wide adoption among the profession. He offered a prize for the best treatise on the action of cold water in fevers, determined by scientific thermometrical study. Dr. Koehlich, a Viennese professor, was the most successful of three competitors, all of whose essays were published in 1823 by Hufeland.

Despite these eminent and enthusiastic advocates, hydrotherapy did not become popular until the appearance of the peasant Preissnitz. His history is doubtless familiar to all. In 1840 he had treated over 1500 patients from all parts of the world by the method he had invented, and when he died, twelve years later, he had amassed several millions.

The impression made by this empiric marks an epoch in the history of hydrotherapy. His success was brilliant, as you know. A copious literature sprang up in all parts of the world, and many institutions were patterned after his. The government

built roads to facilitate access to his establishment; monuments and fountains were erected to his memory. Physicians from all parts of the world, who had been attracted to this Silesian peasant's mountain resort, became converts to and missionaries of his practice.

An interesting chapter in the history of hydrotherapy is furnished by an incident in 1839. Drs. Engel and Wertheim petitioned the French government for permission to erect a hydropathic institution. The petition was referred to the French Academy of Medicine, which appointed a committee consisting of Bouillaud, Velpeau and Roche. The latter delivered such a tirade against hydrotherapy, characterizing it as dangerous, unscientific, chimerical, and opposed to the simplest laws of physiology and pathology, that the sixty members present approved an adverse report amid great applause. On this report the Minister refused to grant permission for the erection of a hydropathic establishment to Engel and Wertheim. These physicians appealed from the decision of the Academy and requested the authorities to investigate hydrotherapy in the hospitals. This was done in the Hopital St. Louis, under MM. Gibert et Devergie in 1841. These made a favorable report, which resulted in the withdrawal of the interdiction previously ordered. Thus has it ever been when the biased views of inexperienced opponents were met by clinical demonstration in hydrotherapy. Bouillaud, the chairman of the committee, recanted.

A few years later Scoutetten was sent to Germany by Marshal Soult to study hydrotherapy. He reported that while it cannot be reckoned a universal method, it exercises an undeniable influence on the public health, and the numerous permanent cures it has wrought on intelligent persons recommend it to popular attention. It lies in the interest of humanity and medical science that the demonstration of the forms and aids of hydropathy in Paris should take place under the eyes of able physicians. This report gave a great impetus to the development of hydrotherapy among French physicians, to whose honor it redounds to-day in the works of Lubanski, Latour, Schedel, Fleury, Dujardin-Beaumetz and others.

Modern fever treatment received its great initiative from Ernest Brand, who in 1861 published his remarkable results from immersions and compresses of water from 50° to 60° F. Bartel and Juergensen are names familiar to the present generation. Vienna became a great center of hydrotherapy, which it has remained under Winternitz, its chief modern promoter.

This rapid, hence imperfect, review brings us down to the present day, and I ask you to listen to what a few of the great clinical teachers of the present day say of that method of treatment which has received the highest enconiums from Hippocrates, Asclepiades, Celsus, Hufeland, and Currie.

Niemeyer, in his book on "Practice," says of it in scrofula: A series of cases are on record in which complete and perfect cure have been obtained by these means after all other methods of treatment had been applied in vain.

V. Ziemssen, the renowned clinical teacher of Munich, says: "It plays an extraordinarily important rôle in tuberculosis, it acts very favorably upon disturbances of the digestion, it is highly valuable in neurasthenia, etc."

Struempell, whose translated work is now a textbook in our colleges, says: "There is at present no other single method of treating typhoid fever, with so numerous and evident advantages for the patient, as the bath."

Prof. Frærtzel, of Berlin, says: "Experience has taught us, up to the present time, that the really brilliant results in the treatment of severe febrile diseases may only be obtained when cold baths form the basis of treatment."

From France we hear the recent utterances of Dujardin-Beaumetz, in his lectures at l'Hôpital Cochin: "The benefits we obtain from cold water in the cure of disease arise from its physiological effect upon the circulation, the nervous system, the nutrition, and from its revulsive and heat-lowering influence."

M. le Pro. Peter, of the Paris School, says, in his preface to the magnificent clinical work on "Hydrotherapy" of Duval, published by Baillière Bros., last year: "Hydrotherapy suffices in most cases of disease; added to other treatment, it is a most powerful auxiliary. Can any one speak better, or say more of it?" he asks.

F. A. Hoffman, in his "Lectures on Therapeutics," published this year, and said by the reviewer —Prof. Ewald—to be the most able work on that subject, says: "*In time all* chronic diseases will come into the domain of the bath treatment, although it is not so much considered now."

Semmola, the Professor of Therapeutics at the Naples School, says very recently, in referring to the value of physical agents for the cure of disease: "The chief of these is hydrotherapy, by which real marvels of recovery in severe and desperate cases are accomplished. It is to be regretted," he continues, "that physicians in general do not accord to hydriatic treatment the value to which it is entitled. Hydrotherapeutics represent in entire series of affections—especially those in which tissue changes are involved, the only effective rational etiological treatment." I might multiply these opinions *ad infinitum*. But I have selected them from men who are not special hydrotherapeutists, but who are teachers of medicine in the best schools of Germany, Italy, and France; men, too, who are known everywhere as representatives of good clinical teaching.

History has repeated itself here, as in other departments. The opinions of the most judicious, philosophical, and successful physicians of past ages have been sustained by the judgment of the most enlightened era.

47 East 60th St., New York.

The *Epicure*, in setting forth the virtues of coffee, claims that it is unequalled as a stimulant, being the best substitute for spirits in rescuing the drunkard from his cups. It is a preventive of malaria and epidemics, and a specific in typhoid fever. As a disinfectant it has popular favor.

The Polyclinic.

MEDICO-CHIRURGICAL HOSPITAL.

MITRAL DISEASE.

THIS man, age forty-eight years, a tinsmith by trade, for the last two weeks has had swelling of his legs. Twenty-years ago he had an attack of rheumatism, but the swelling he had at that time is unlike this. There is no pain or redness, and the part is rather cooler than normal. He has been a drinking man. The tension of the skin is marked; the leg is white and milky in appearance; there is sensation of yielding to the fingers, and pitting on pressure. In cases where this swelling becomes extreme the skin bursts, and a limpid liquid like the serum of the blood escapes. This is a trouble formerly classified as the disease dropsy, but is now regarded merely as a symptom. The common causes are affections of the heart or kidney; obstruction to the venous circulation. I find his pulse is weak and irregular, and deficient in tension. He has a systolic murmur, which is the result of a past rheumatic endocarditis, followed by deficiency of the valve with some hypertrophy. There is no albumen in the urine, but it would not have been surprising if there were some here, due to the heart weakening, which allows of transudation of albumen. Kidney symptoms are negative. Probably his blood is not in a very good condition, for he appears anæmic. Under these circumstances see that he is well fed. Do not throw any unnecessary work on the heart as it is now working at double its normal rate. He must also have something to strengthen his heart, increase his appetite and improve the blood. Patient should eat red meats in the middle of the day, and should abstain from pork, mutton or heavy foods. Milk three times a day. We will give him one drop of a one per cent. solution of nitro-glycerin thrice daily to increase the tension of the heart. Also order:

℞.—Tr. gentian. comp . . . . . ʒ ij.
Sodii bicarb . . . . . gr. ij.
Syrupi zingiberis,
Aquæ . . . . . āā ad ʒ ss.
To be taken at one dose.

—*Dr. Woodbury.*

CROSSED HEMIPLEGIA.

Here is a very interesting case of nervous disease that has been brought into the hospital. The patient is a man forty-five years old, and a hard worker. He is a Swede, and an instrument maker. While at work he was suddenly taken with a queer feeling in his head, had to sit down, and soon lost power of expressing himself, while the right side of the body became paralyzed. When he came here the right arm and leg were paralyzed, along with the left side of his face; he had a crossed hemiplegia. He is unmarried. He can talk now, but the mouth draws to the right side, for the muscles of the right side act, while those of the left do not. There is decided loss of sensation on the right side; he scarcely feels the stick of a pin, but he is quite sensitive on the other. There is no difference in temperature on the two sides of the body. Examining this case farther we find that he had no headache when this attack came on last week. It came in the morning in his right hand, and by evening he had lost the power of the right leg also. He was conscious all the time. The strangeness of his speech consisted in the loss of all articulate language, but at the present time there are some words which he cannot say at all. This is not due to paralysis of the tongue or larynx, but because he can not firmly coördinate in his mind. It is a condition of aphasia.

I will also add to his history that he had a bad attack of pyæmia, and as often happens there was an endocarditis, and a disturbed function of the valves. There is a murmur with the first sound, and one with the second at the aortic orifice. He has left sided endocarditis, and as a result of this has had deformity of the valves, and formation of clots, or fibrinous polypoid granulations. It is possible that one of these has been carried to the brain. We know that in crossed hemiplegia the clot must lodge low down in the brain, beyond the decussation of the facial nerve. Hemi-anæsthesia is a lesion of the optic thalamus or the fibers that pass through it from the opposite side of the body. It involves a multiple embolism. One embolus affects centrally the optic thalamus at its anterior portion, and the other the decussation.

An effusion of blood would have been apt to cause pain, loss of consciousness, vomiting and involuntary discharges. Congestion is negative from the absence of headache. Right eye is defective in refraction. The treatment of this case requires first of all rest and mild stimulating diet. Keep the bowels regular, and administer potassium iodide, gr. v, at a dose, and increase it gradually to gr. xx–xxx. With this, spts. ammon. aromat. ʒj, three times a day, as it is an antidote to iodism and dissolves the clots and concretions. If we find his pulse subnormal and its tension not good we will put him also on digitalis. We will not use electricity, for it is yet too soon.—*Woodbury.*

PHILADELPHIA HOSPITAL.

DOUBLE HÆMATOMA.

I WISH to call your attention to this child, as it is a curiosity. It is a case of double hæmatoma occupying both parietal bones. One month ago I had a child that was born at the Maternity Hospital with this same condition, and I am inclined to think this is the same child. This condition occurs once in fifteen hundred to two thousand cases. The deformity at birth in this instance was very marked, but it is now gradually disappearing. By pressing the fingers upon these blood tumors you can feel the bone under them, and thus diagnose them from a meningocele. The treatment is to let them alone, as they become absorbed in five or six weeks. In the rare occurrence of suppuration they must be opened. Unilateral hæmatomas occur in about one case in two hundred.

Note.—The child died one week later from acute congestion of the kidneys.—*Hirst.*

NAUSEA may be relieved by applying cold to the back of the neck.

THE NEW ANALGESICS IN THE RELIEF OF PAIN OF PURELY NERVOUS ORIGIN.

ANALYZED to the last degree, the practice of medicine consists solely in the relief of pain. Not only is this "a divine work," as Hippocrates used to say, but it is doubtful if medicine, as an art and science, would have any existence whatever if there were no such thing as pain. Were it not for the warning sounded by this symptom, we should die like the flies, without being able to summon timely aid. Even as it is, many a deadly disease advances far in its course before the slight symptoms of pain drive the sufferer to seek medical advice and so have the real nature of his condition made known. Pain, in this respect, is a blessing rather than a curse. Owing to the smallness of human knowledge, it is to be regretted that the causes of pain cannot always be discovered. The symptom, as in idiopathic neuralgia, may be excruciating, but the lesion totally unknown. In such cases the symptom alone must be relieved. Not unfrequently, however—as in tabes—the lesion is perfectly familiar and possibly amenable to cure, but the fulgurating pains are so terrible to bear that the latter must needs be relieved, for the time being at least, irrespective of the nature of its cause, or the latter's susceptibility to treatment.

Analgesics, therefore, have always held an honored place among therapeutical resources, but heretofore nothing has been able to approach opium and its alkaloids in this respect. The danger of causing the opium-habit, which is unfortunately becoming too frequent nowadays, induces many of our best physicians to dispense with the drug almost entirely, or to employ it at rare intervals and in extreme cases. Morphinomania is a disease for which practitioners themselves are not a little responsible; and it is to be hoped that they will become hereafter even more cautious in their use of these dangerous preparations of opium.

Atropine was the first drug tested with the introduction of the hypodermic method of medication, but the intolerance manifested by some constitutions, along with the occasional fatal results which followed its use, have caused it to be laid aside.

Solanine possesses many advantages in certain spinal affections, particularly in the systematic scleroses of the cord, when accompanied with pain and trembling; but its effects are limited.

Aconitine is a powerful analgesic. but it seems to exercise its force when administered in safe doses only in cases of facial neuralgia. It seems to be absolutely powerless in removing pains due to spinal cord lesions.

We are in need, therefore, of more safe, reliable, and effective analgesics that will cause simply a disappearance of pain, without otherwise injuriously affecting the constitution.

In the last number of the *Bulletin de Therapeutique*, Dujardin-Beaumetz presents a brief and practical resumé of the more recent preparations of this class, and offers some remarks upon their relative values in relieving the pains of purely nervous origin. We published (TIMES AND REGISTER, October 5, 1889) not long ago a long abstract of this same author's report to the Congress of Therapeutics upon the chemical constitution of these bodies.

Germain-Sée, in 1887, was the first to recognize the analgesic power of antipyrine or dimethyloxyquinizine. Since that time it has been employed and successfuly tested in so many painful affections that one is almost prone to regard it as a kind of panacea. But especially is it valuable in diminishing the excito-motor power of the cord and in curing the lightning pains of locomotor ataxia. Dujardin-Beaumetz recommends that the dose should never exceed two or three grammes a day, and if this fails to remove the pains, one of the other analgesics had better be resorted to.

Marshall says that antipyrine appears to be a specific in some diseases—as in gout and migraine. In fact, it would be vain to attempt to enumerate all the cases in which success has attended the use of this drug for the relief of pains. Hypodermatically administered, it is more decisive in its action than when given by the mouth. Some observers, like Hirsch, have been disappointed with it when exhibited by the stomach, but when administered subcutaneously they prefer it to morphine. The majority of clinicians prefer the use of small doses by the mouth frequently repeated; and it is always well to tell the patients to lie down after taking it, particularly if they take it in large doses. Weakness of the circulation and disease of the kidneys are the special contraindications against its use.

Phenacetine was first employed, in 1887, by Kast and Hinsberg. There are three varieties, known as ortho-, meta-, and para-acet-phenetidine, the latter being the one most generally prescribed. It is a white, rosy powder, insoluble in water, but slightly

soluble in chloroform and alcohol, hence it is best administered in wafers or papers. Fifty centigrammes, repeated two or three times a day, acts like antipyrine or acetanilide in causing the disappearance of pains, whatever may be their character. Singularly enough, this preparation also combats the polyuria as well as the excito-motor functions of the cord. The insolubility of phenacetine is one of its most important disadvantages, and for this reason it is not as available for general use as some others of the same group.

Methylacetanilide, or exalgine, is the latest of these medicaments, and excepting antipyrine, promises to be the most valuable. It appears under the form of beautiful colorless crystals, which are slightly soluble in cold water, but on the other hand are very soluble in alcohol, and even in a mixture of alcohol and water. They are devoid of taste or odor. This substance is an antipyretic, lowering the temperature from one to three degrees, and even more. It also increases the arterial tension and vascular pressure. Its first action is manifested within the nervous system, both sensory and motor; then in the respiratory and circulatory systems, and finally in the heat apparatus. In doses of eighty centigrammes it produces intoxication and vertigo; tolerance, however, can quickly be established. As an analgesic it takes rank with antipyrine, and is sometimes superior both to it and acetanilide.

In the last number of the *Therapeutic Gazette* it is said that "the analgesic effects of exalgine are especially evident in the treatment of neuralgia, and to a less reliable degree in the treatment of pains of a rheumatic character."

In conclusion, then, of all the modern antithermic analgesics, antipyrine holds the first place, both for its efficacy and ease of administration. Despite the occasional scarlatinal eruption, profuse sweat, and collapse which follow its ingestion, it is no more dangerously toxic than other drugs, if it be administered in doses not exceeding three grammes in the twenty-four hours, and in properly selected cases.

Next to antipyrine comes exalgine, and if the latter were only more soluble, it would be given the preference. It is better to administer this drug in small doses—say twenty-five centigrammes twice a day. An ordinary tincture or alcoholic solution affords an excellent menstruum. In the treatment of neuralgia, Gaudineau experienced only three failures with exalgine, in thirty-two cases. In cardialgia, with attacks of angina, it has acted favorably. In fact, it is praised as the most certain and decided destroyer of pain that we have, irrespective of the origin of the pain.

Because of its extreme insolubility, phenacetine ranks below antipyrine and exalgine. For the same reason, therefore, it is advantageously the most nontoxic of the present group of remedies. It is especially commendable in doses of fifty centigrammes to a gramme, given in powders, to relieve the shooting neuralgias so common among hysterics and neurataxics.

Last of all should be remarked acetanilide, not because it is less powerful than the others, but because of the alarming cyanosis which it produces. It is both active and cheap, and can be easily administered in the form of powders in doses of a gramme to a gramme and a half in the twenty-four hours. The best results with this preparation, as an analgesic, have been obtained in relieving the fulgurating pains of tabes dorsalis. In a few instances of epilepsy it seems to have afforded a cure. But in this class of cases there have been, as usual, frequent failures; nevertheless, when the bromides lose their effect, and the patient is able to bear it, Dujardin-Beaumetz recommends the habit of ordering acetanilide.

Such, in brief, are the more important properties of these new analgesics, and instead of our decrying the recent increase in this respect, we ought to encourage their introduction, and their further careful study. They promise to place at our disposal medicaments that have been long needed, and are more advantageous than any of the same class that we have hitherto employed; but there is need of greater care and precision in the testing of their exact physiological actions, in order to fix their value, and to establish the realization of that promise.

THE MYCOTIC ORIGIN OF INFANTILE DIARRHŒA.

THE sad procession of victims from the summer diarrhœa of infants continues from the first days of high atmospheric temperature to the early part of autumn, which are signalized by a more temperate condition of the atmosphere. The labors of the men who are determined to diminish the mortality among the most tender of our population continue unabated. There is a glimmer of hope upon the horizon; the solution of the problem approaches slowly, but, we trust, surely.

Two recent contributions to this subject are of interest as designating the direction in which we must seek the conditions of therapeutic success.

Before the Pædiatric Section of the recent Heidelberg Congress, Escherich, who has already contributed a considerable fund to our knowledge on infant feeding, said that bacteria certainly play a prominent rôle in the pathology of the derangements of the digestive organs of infants, although up to the present time there has been no specific bacillus discovered. There is no doubt, however, that in infants those derangements are to a great extent due to the food, the chief element being the fermenting activity of milk, which is encouraged by high temperatures. There are, according to Escherich, two forms of fermentative dyspepsia: an ectogenous and an endogenous. The former occur only in infants reared on cow's milk; they are the lactic acid dyspepsias, run-

ning their course at the expense of the sugar. If decomposition ensues in a moderate atmospheric temperature, the resulting elements are milk sugar and carbonic acid: in high temperatures abnormal acids, alcohol and toxic elements are formed, which produce nervous disturbances. Escherich has discovered that an essential difference is noted between moderate and high temperatures. And this is an important element in the solution of the difficulty, and it is brought out also in a recent paper by Baginsky, who refers to the fact that Virchow had recently said that, although the mortality of infants under one year is dependent upon the temperature, it also stands in relation to the lowering of the river water in summer.

In Berlin Baginsky has observed just what has been clearly shown in other large cities? that the summer months chiefly increase the mortality of infants. It is not only the high elevation of the atmospheric temperature, but the prolonged duration in the dwellings which is responsible for this lethal effect. Virchow has called attention to the point that the fault lay either in the food or water, and therefore Baginsky is inclined to infer that bacteriological processes bear a large share in these conditions.

In order to decide whether we have specific disease germs or simple saprophytes, Baginsky examined twenty-five cases of cholera infantum bacteriologically, without finding a single bacterium; hence he concluded that cholera infantum is a genuine saprogenous affection. The chemical action of all the forms of bacteria he found indicates that the substances produced by them possess a fearful toxic action, so that animals would be killed by subcutaneous injections with them in a few minutes. Like Brieger's ptomaines, they produced fibrillary contraction of the muscles, tetany and death.

Baginsky deems it probable that the cholera-like manifestations are due to the influence of the large quantities of ammonia in the fæces, as well as to the ptomaines.

The endogenous form of dyspepsia and diarrhœa is, according to Escherich, attributable to the comparative lack of hydrochloric acid in the infantile stomach, which diminishes its anti-mycotic powers. In his investigations he found some hydrochloric acid in the stomach of breast-fed infants, but none in those fed with cow's milk. Stomach digestion is, in high temperatures, according to Escherich, only a continuation of the ectogenous fermentation; toxic substances and abnormal acids forming. The same thing is continued in the duodenum, except that there is no oxygen, and only anaërobic bacteria may exist here. In the stomach and duodenum we have only saccharine fermentation. In the lower portion of the intestinal canal the conditions change; we have here alkaline fermentation, whose end products are ammonia and carbonic acid.

In the discussion of Escherich's paper, Sonnenberger brought out the fact that there exist in clover fields many poisonous weeds, whose alkaloids, when they are taken fresh, may enter the milk and produce a toxic gastro-enteritis.

A careful survey of the field brings us to the inevitable conclusion that the food is the chief source of those toxic processes which originate from the unfavorable influence of high atmospheric temperatures upon it. It is clear, therefore, that the solution of the problem lies in prophylaxis. That artificial feeding and high temperature are the predominant factors in infantile diarrhœa has long been demonstrated, but the interaction of these two elements becomes of importance under modern investigation. The sterilization of milk alone offers us a positive hope. Soxhlet's apparatus has proved efficient, but only to a certain extent. While it doubtless contributes partly to the purification of milk, it is not by any means perfect. Shrœder, Von Dusch and Pasteur have clearly shown that nothing short of a temperature of 130° C. (266° F.) for half an hour will completely sterilize milk.

How far short any domestic arrangement must fall from this standard is evident. So is the remedy, to which we will recur in a subsequent issue.

Annotations.

A NEW JOURNAL.

THE *Medical Mirror*, a new monthly, to be edited by I. N. Love, M.D., will first appear in January, 1890. Its object will be to correctly reflect the medical profession of to-day, and its accepted advances. It will labor for the interest of the profession of the Mississippi Valley, but, at the same time, will be cosmopolitan. Remembering the well-known ability and the large number of friends of Dr. Love, we bespeak for the *Mirror* a large list of subscribers. We shall look with pleasure for the advent of this newcomer to our exchange table.

A NEW ANTISEPTIC.

THE important address on a new antiseptic dressing, which Sir Joseph Lister delivered before the Medical Society of London on the 4th inst., in spite of its modest title, carries on the history of the author's work from the date—now five years ago—when he last addressed the Society. At that time he had shown not only that corrosive sublimate formed a compound in the albumen in which the properties of the former were preserved, but that this compound, even after drying, was capable of dissolving in blood serum. Hence came the sero-sublimate gauze, which had a definite and admitted value. But certain defects soon revealed themselves in the gauze, which was somewhat harsh and not very absorbent. So the investigator pushed on, and sought for new agents. The first that offered was substantially the double chloride of mercury and ammonium, called sal alembroth. This presented great advantages; it was a better antiseptic, and at the same time was less irritating than corrosive sublimate. But again objections turned up, for the compound was so soluble,

not only in water but in serum, that when the discharge was considerable, too much of the mercurial compound got to the edge of the dressing, and great irritation was caused. So another start was made with cyanide of mercury. This was found to be, in the author's language, high as to inhibitory, but low in germicidal, power. But it was irritating as well as very soluble, and the double cyanides—of which, without counting such bodies as the ferrocyanides, there are many—were next tried. Mr. Martindale suggested one of the insoluble double cyanides of mercury and zinc; such a compound has proved superior to all other substances hitherto used. There seems indeed some doubt as to the precise compound which exists in the preparation which is now used; but it is certain that the mercury in it is an important though not in quantity a large factor. The very ingenious method by which, after many trials, the substance was incorporated with starch, with which it forms a kind of combination whereby it can be affixed to gauze so neatly that in the dry state it does not become detached, and in the wet state does not wash away, and the apparently perfect success of the gauze, which is at once antiseptic, porous, permanent, and non-irritating, the address describes in detail.

But even the zinc mercury cyanide was not immediately successful, and some early difficulties caused it to be for a time abandoned. Then the patient investigator turned his attention to iodide of mercury. This is known to have antiseptic powers, and is besides very sparingly soluble in water. It is more soluble in blood serum, but then it is very irritating and difficult to fix to the gauze. The latter objection was removed by the employment of starch, then tried for the first time. Here, as with the double cyanide, a loose kind of molecular combination seems to take place, and the iodide does not dust off. But still the experimenter was not satisfied, and therefore, with the experience gained from the starch experiments, fell back on the double cyanide, with which, under carefully prescribed conditions. he is for the present contented.—*Lancet.*

Is Man Left-legged?—Dr. W. K. Sibley read a paper before the British Association in which he argued that man was naturally left-legged. Standing working with the right hand, there was a tendency to balance on the left leg. Race paths were nearly always made for running in circles to the right, and the majority of movements (such as dancing, running, etc.) were more readily performed to the right. In walking, it was natural to bear to the right; crowds as well as individuals did so. Troops started off with the left foot; the left foot was placed in the stirrup or step of the bicycle in mounting; the left foot was the one from which a man took off in jumping. From measurements made by Dr. Garson of the skeletons of the two legs, in 54.3 per cent. the left leg was the longer, and 35.8 the right. From measurements of two hundred pairs of feet, it was found that in 44 per cent. the left, and in 21.5 the right, was longer, while in 34.5 they were equal.

Letters to the Editor.

TREATMENT OF PHTHISIS PULMONALIS.

It has been the aim, so far, to devise means either to destroy or render inert the tubercle bacilli, and the suppuration process has been left to itself, unless we are to consider that reconstructives will, in a measure, terminate it. The fact that bacilli being present in the sputum is pathognomonic of the tuberculosis, does not prove their existence to antedate the disease. I do not wish to be understood as denying the contagiousness of the disease, but contend that the contagion is limited consonantly with the physical powers of resistance, and as this is influenced by our environments or heredity. If there is any hereditary lack of the power to resist morbid influences, and we are exposed to the contagion of phthisis, then we will be subjected to the consequences.

On the other hand, if our environments are conducive to disease of the lungs, then the result will be the same—tubercle bacilli always being present. However, be this as it may, what I wish to say is in regard to the use of calcium sulphide as an agent in the treatment of phthisis pulmonalis. I have used it in a few instances, and have two new cases under treatment with this alone. I find that it arrests the suppuration process in the same manner that it does in boils. I am using it now in a case of gastric ulcer with benefit.

I find that in disease of the lungs the appetite grows better, the cough is lessened, and expectoration is easier. Hemorrhage grows less frequent, or disappears, and sleep is more tranquil and refreshing. I give one-quarter to one-half grain three times daily, either in sugar, or milk, or suspended in syrup. Plenty of good food and no alcoholics of any kind. The remedy should be persisted in, and not discontinued after a few days. In conclusion, I make special request of any one trying this plan to report to me the results, for it is clinical facts that we want, and we can pin on a theory afterwards. I will be pleased to correspond with those whose opportunities are wide for trying the experiment, for such only it is for the present.

E. Houston, M.D.

Stanberry, Mo.

WHAT WAS THE TROUBLE?

Believing it desirable that all anomalous or exceptional cases should be published as guides to the practitioner, just as rocks and quicksands are marked on charts for the avoidance of the mariner, I present this unavoidably imperfect account. The experience was that of another physician.

According to his recital, the patient was one who had been ill long enough to have made use successively of the services of a dozen doctors, though for just what length of time he did not know. This physician found the man afflicted with almost total paraplegia, and with complete anæsthesia of the affected portions. There was loss of sexual desire and ability; but the bladder and the rectum were unaffected.

My friend, finding the case too obscure, took as consultant one of the foremost nerve specialists of this city. He also was unable to arrive at a diagnosis, but wavered between hysteria, posterior spinal sclerosis, and syphilis. Though the history seemed completely to exclude this latter disease, it was decided to put the patient on a tentative treatment of potassium iodide, and to increase the dose to as much as he could stand. He was finally given eighty grains a day. Although it would seem extremely probable that this must have been tried before, yet the patient rapidly improved.

When well advanced towards recovery, his physician, for some intercurrent trouble, gave ten grains of calomel, followed by a dose of olive oil the next morning. This unexpectedly brought away a foot or two of a *tænia solium*. Starting on this new scent, so to speak, my friend, by means of a full dose of oil of male fern, expelled the entire parasite. After this the patient improved like magic and has for months been perfectly free from any similar trouble.

His physician's query is now this: Since syphilis seemed to be utterly out of the question, were not the nervous phenomena due to the tape-worm, and did not the large doses of iodide of potassium improve his condition by affecting the worm rather than its host?

PHILADELPHIA, PA. ERNEST B. SANGREE, M.D.

Society Notes.

THE SOUTHERN SURGICAL AND GYNÆCOLOGICAL ASSOCIATION.

Second Annual Meeting held in Nashville, Tennessee, November 12, 13, and 14, 1889.

NOVEMBER 12.—FIRST DAY.—MORNING SESSION.

THE Association convened in the Senate Chamber, and was called to order at 10 A.M. by the President, Hunter McGuire, M.D., of Richmond, Va.

DR. R. B. MAURY, of Memphis, contributed a paper entitled

REPORT OF GYNÆCOLOGICAL WORK, WITH ESPECIAL REFERENCE TO METHODS.

The paper presents a brief summary of the more important portion of his operative work during the past year. With four exceptions all of the operations reported were done in a private hospital, built especially for the purpose, and under his own control. The summary embraces twenty-one laparotomies for the removal of ovarian tumors, or of the uterine appendages, or for the relief of obscure disease within the abdomen; two laparotomies for ectopic gestation; twenty-eight operations for laceration of the cervix; fourteen perineal and vaginal prolapse operations, five rectoplasties; four interior colporrhaphies.

Dr. Maury summarized the methods as follows:

1. An aseptic field of operation, and an aseptic surgeon.

2. A small incision—in the case of infiammatory disease in the pelvis, just large enough to introduce and work with two fingers.

3. Aseptic silk ligatures, as fine as may be consistent with safety in tying.

4. Enucleation of diseased structures, in spite of firm adhesions, and even profuse hemorrhage.

5. Irrigation by means of the siphon-trocar as a substitute in most cases for sponging. Using simple hot water for this purpose, and excluding all antiseptics.

6. Drainage often, and whenever one is in doubt as to its necessity.

7. Careful replacement by spreading out of the omentum before proceeding to close the wound.

8. Inclusion of all the structures in passing the abdominal wall sutures; and placing the deep sutures one-half an inch apart.

9. The use of means for moving the bowels on the second or third day, after removing the appendages; and the avoidance, if possible, of opium.

Discussed by Drs. Wathen, Price, Stone, Potter, and Johnstone.

DR. W. O. ROBERTS, of Louisville, Kentucky, read a paper on

DIRECT HERNIOTOMY,

in which he reported ten cases, and did eleven operations. Seven cases occurred in females, three in males. Three were cases of umbilical hernia, three were femoral, three inguinal, and one ventral. Six of the operations were done during strangulation, while five were performed for troublesome, irreducible hernias. In the six cases of strangulated hernia, the sexes were equally represented. Three were inguinal, two femoral, and one umbilical. In five of them, the operation for radical cure was done. The remaining case was one of strangulated hernia, where stercoraceous vomiting existed for eight hours before it was seen. General peritonitis was evident at the time of the operation. Much reddish stuff escaped when the contents of the sac were returned. Death followed in thirty-six hours. He had since thought that, if, after returning the contents of the sac, he had done a low median laparotomy and washed out the peritoneal cavity, the result might have been different.

The four cases of irreducible hernia were all in females. Two were umbilical, one femoral, and one ventral. In one of the former, a second operation was made necessary by the hernia recurring at the end of six months. The tumor also re-formed at the end of ninety days, in the case of femoral hernia. The remaining eight cases continue well to the present date.

In all the cases the sac was first cleanly dissected out, and not opened until all hemorrhage was entirely checked. Both in the ventral and umbilical hernias, the integument and fascia were divided by an elliptical incision. After opening the sac, all adherent omentum was tied with catgut and excised. The remaining contents were then returned into the cavity. In one case of umbilical hernia, the neck of the sac was tied close to the margins of the opening, and cut away immediately in front of the ligature. The stump was then fastened tightly in the opening with silk worm gut sutures, and the wound finally closed by interrupted sutures of the same material. In this case, no suppuration occurred, but the hernia recurred at the end of six months. In both the other umbilical and in the ventral hernias, the neck of the

sac was excised on a level with the abdominal opening and sutured with catgut. The opening itself, after its edges were freshened, was closed with the continued suture of chromatized catgut in the ventral hernia, and aseptic corded silk in the umbilical cases. The superficies were brought together by silk sutures, which were continued down to the aponeurosis.

In the femoral hernias, he adopted the practice of Mitchell Banks. In the cases of direct inguinal hernia, after tying the neck of the sac just within the ring, and removing all in front of the ligature, the ring was closed with catgut sutures.

In the cases of oblique inguinal hernia, he did Mr. Ball's operation, which consists in freeing the neck of the sac up to the internal opening, ligating it, cutting away all in front of the ligature, then twisting the neck upon itself to effect closure of the peritoneal orifice, and finally stitching the stump to the pillars of the ring to guard the neck against untwisting itself.

Dr. Virgil O. Hardon read a paper entitled

THE ABORTIVE TREATMENT OF ACUTE PELVIC INFLAMMATION.

He said the views held by gynæcologists in regard to acute inflammation in the female pelvis have within the past few years undergone a radical change. The inflammatory processes formerly regarded as idiopathic, or at least as primary affections, are now almost universally recognized as dependent upon antecedent disease in the ovaries or Fallopian tubes, especially the latter. This change of opinion has to a large extent been due to the result of advances in surgery, which have enabled the conditions of the pelvic organs to be studied in the living subject by immediate inspection and palpation, instead of through the medium of the vaginal tissues; consequently it is evident that a change of opinion on this subject has been most marked among those men who have had large experience in abdominal work. The diagnostic value of abdominal section under such circumstances is almost as great as that of post-mortem examination, and hence the opinion of the laparotomist is entitled to very great weight. As a result of this mode of observation the conclusion cannot be avoided that acute pelvic inflammation is, at least in the majority of cases, associated with septic, gonorrhœal, tubercular or some other form of inflammation of the tubes. There are two forms of inflammation which are recognized as occurring within the pelvis as a result of tubal disease, pelvic cellulitis, and pelvic peritonitis. In many cases both forms of inflammation are simultaneously present in the same subject, and it is not improbable that in all cases when either is present, the other also exists in a greater or less degree.

It is hardly possible, when one considers the anatomical relations of the pelvic cellular tissue to the peritoneum, to conceive of an inflammation of the one structure without a greater or less implication of the other. In the majority of cases one form of inflammation can be recognized as forming the preponderating element of the disease, to which the other plays only a secondary rôle.

The constitutional symptoms consist of acceleration of the pulse, elevation of temperature, severe pain in the pelvis extending down the thighs, tenderness of the hypogastric region, a sense of weight and fulness in the pelvis, difficult micturition, painful defæcation. These symptoms are most marked in the acute stages, and are somewhat diminished as soon as solidification has taken place. They continue, however, with lessened intensity into the third stage of the disease.

The treatment consists in the withdrawal of the effusions from the cellular tissue by means of the aspirator, etc. Where pus-tubes are present he would advocate their removal.

Dr. Joseph Price, of Philadelphia, said his experience was a little different from that of the essayist. Relief from salines and the aspirator in the cases reported, may have been justifiable, but pus-tubes in every instance call for abdominal section. He then exhibited some pus-tubes, one of which was seven inches in length, and called attention to their frequency in cases of pelvic inflammation. He said, thirteen years ago, a woman living in Pottsville was treated by a prominent gynæcologist for pelvic peritonitis. Sponge tents were used, and the patient made a doubtful recovery. Eight years ago Dr. Goodell effected drainage through several sinuses then existing, three or four being about the sacral region, two or three in the groins, and one in the anterior abdominal wall. Six weeks ago Dr. Price evacuated two gallons of pus in the same patient. A perfect recovery was brought about in some of his cases only by abdominal section and the removal of pus-tubes. The history and symptoms in his cases were identically those mentioned by Dr. Hardon. In the light of our present accurate knowledge, acquired by a large experience in the pelvis, the conclusion is that the entire subject of pelvic peritonitis and cellulitis will have to be rewritten. The sharp distinctions between the one and the other are refinements that the surgeon no longer seeks. Peritonitis, the result of tubal and ovarian disease, is exceedingly common. Gonorrhœa is the most common cause of all.

Dr. Geo. Engelmann, of St. Louis, said there was a fascination in the results achieved by Dr. Price, and other operators, but he thought the pendulum was swinging too far in that direction, He could endorse the surgical treatment advocated by Dr. Price, in dealing with cases of pelvic inflammation, which result from salpingitis, or where there was pus in the tubes. Many of the cases which were formerly called pelvic cellulitis are the sequences of salpingitis or pus in the tubes, and he was satisfied there are cases which exist without salpingitis.

Dr. W. G. Ewing, of Nashville, said that when he began to practise he was on the conservative side, but is satisfied that many of the cases which came under his observation could have been dealt with surgically and successfully. He favored early operative interference, and said the surgeon should not delay in such cases, for by so doing additional adhesions were apt to form with extension of the inflammatory process.

Dr. Hardon, in closing the discussion, said he feared he had been misunderstood, but would now

say that pus-tubes admitted of but one rational treatment, and that was their removal. He invariably recommends this to be done, but what should the surgeon do with those patients who will not permit an operation?

As regards pelvic cellulitis, without disease of the tubes, he could corroborate the statements of Dr. Engelmann, and called attention to two cases he reported last year to the Association which verified the fact. In these cases he separated and withdrew several drachms of serum from the cellular tissue. Subsequent examination revealed absolutely no disease of the tubes. He has examined these patients from time to time, but not the slightest evidence of tubal disease could be found, and there has been no recurrence of the pelvic inflammation.

Dr. W. D. Haggard, of Nashville, read a paper on

THE IMPROVED CÆSAREAN SECTION VERSUS CRANIOTOMY,

in which he said that the improved Cæsarean section offers justifiable means of saving both mother and child, and relieves the heart and conscience from the charge of scientific murder. Embryotomy on a living child will soon cease to be regarded as a scientific, or even a justifiable operation. This seems to be foreshadowed by the statistics of Caruso, who reports a case in detail by Sanger, and one by Sweiffel, and adds statistics up to October, 1888, comprising one hundred and thirty-five. Six successful cases were known in addition to Caruso, but the details necessary for publication were lacking. German operators have performed seventy-four of these operations, Americans eighteen, Australians sixteen, the results obtained by the American surgeons being inferior to those of German and Austrian operators. The results show a large per cent. of recoveries among mothers in all cases, and a still larger per cent. in the case of children. In three cases in which the operation was done a second time, both mothers and children recovered. A careful estimate of the results of craniotomy under antiseptic precautions shows that 93.04 per cent. of mothers recover. Selecting similar cases on which section was performed, the percentage of recoveries in these cases was 89.04; and 100 per cent. of children.

Afternoon Session.

Dr. W. H. Wathen, of Louisville, read a paper entitled

THE TREATMENT OF ECTOPIC PREGNANCY.

This paper was followed by impromptu remarks on

PERINEORRAPHY,

by Dr. A. W. Johnstone, of Danville, Ky.

Dr. Joseph Price, of Philadelphia, contributed a paper on

PUS IN THE PELVIS, AND HOW TO DEAL WITH IT.

By pus in the pelvis he meant pus that has its *fons et origo* in the pelvic organs or their investment. The rarer causes of pus in the pelvis may be said to be: 1. Carious bone, as psoas abscesses. 2. Traumatism, sloughing, results of electricity, direct violence, etc. 3. Foreign bodies, as extrauterine bones, etc. The general rule is that pus in the pelvis is always the result of diseased conditions of the uterine apendages, whether it occurs as a result of a ruptured extrauterine pregnancy, a suppurating ovarian or dermoid cyst, or salpingitis caused by gonorrhœa, parturition, dirty instruments, electricity, or what not. In general then, when the surgeon finds pus in the pelvis, he will find its origin in the uterine appendages. He had seen pus discharging from the rectum, from the bladder, the umbilicus, and from the vagina. He had seen psoas abscess, perforating appendicitis, idiopathic peritonitis, and typhoid fever, and found the seat of trouble in the tubes and ovaries. In all his experience he had never seen pus in the pelvis independent of the disease of appendages. To make the statement definite, he had seen more than once double pyo-salpinx and double ovarian abscess contained in a pus pocket in the peritoneal cavity composed of adherent intestines and inflammatory tissue, four abscess cavities contained within a fifth. Again, he has seen a single pus-tube with four distinct pockets in it. Pus can burrow through the cellular tissue and find vent, as before stated. How shall pus in pelvis be treated? The general principles of surgery for the treatment of pus in any other part of the body, apply with equal force to the pelvis. Namely, where pus is present evacuate it, and secondly, remove the cause of the suppurative process. It is equally unsurgical and unscientific to allow pus to remain in the pelvis, as it would be to allow it to remain in the brain, in the mammary gland, or under the fascia in any part of the body. It is equally unsurgical to allow a suppurating tube or ovary to remain in the pelvis, as it would be to allow a sequestrum of dead bone, or to allow a necrotic placenta or membrane to remain in the uterus. These principles do not admit of evasion. All sorts and kinds of treatment have been tried without avail. Every man of experience knows the futility of counter-irritation, local depletions or a general systematic treatment in the vast majority ef cases.

There are only three methods of treatment common to physicians to-day: namely, electricity, vaginal drainage and abdominal section with the removal of the diseased parts, thorough irrigation of the peritoneal cavity and drainage.

The first of these methods need scarcely be mentioned in cases where pus is already present. Electricity has no place in the treatment of pus in the pelvis. Vaginal drainage is a crude, inefficient method, and is not so safe as some would have us believe. In abdominal section we have the quickest, easiest, most exact, and therefore safest mode of treatment for pus in the pelvis. A small incision, rapid enucleation of the offending tubes and ovaries, the breaking up and evacuating of the separate pus pockets, the separation of adhesions, the thorough washing out of the peritoneal cavity by copious irrigations of warm distilled water, the placing of a glass drainage tube in the most depending portion of the peritoneal cavity, and the careful closure of the abdominal incision, gives the patient the quickest relief, permanent cure, and very often snatches her from an

impending death. Moreover, here we attain the most ideal treatment; for in no other point of the body can we enucleate completely an abscess with its containing walls and pyogenic membrane. However, we should always bear in mind that the province of the surgeon is, first, to save life, then to relieve suffering, rather than to perform ideal operations. Many patients dying with pus in the pelvis need but a feather's weight to depress the beam. In such cases the indications are to evacuate the pus, wash out the cavity and wait until a future time to remove the offending cause.

Discussed by DRS. HARDON, ENGELMANN, STONE, ROBINSON, HADRA, and POTTER.

DR. W. L. ROBINSON, of Danville, Va., read a paper on

GYNÆCOLOGY IN ITS RELATION TO OBSTETRICS,

in which he spoke of the cervix uteri in its pathological condition predisposing to hemorrhage prior to labor, laceration, and septic absorption. He could find no explanation in medical literature of the cause of ulceration of the cervix, non-specific and non-malignant, causing hemorrhage in two cases which came under his observation within the last twelve months. He used the word "non-specific" because of the perfect health of the patients prior to the pregnancy and since delivery, his knowledge and intimate acquaintance for years with husband and wife. The first case was seven months advanced and spending a summer in the mountains for the benefit of one of her children. She found herself unwell after a week, and the flow was sufficient to soil the clothing and require napkins. A physician was called, who gave ergot and opium, which controlled it in twenty-four hours. Two weeks subsequently the conditions repeated themselves and relief was obtained by the same remedies. She returned to the city and was again annoyed by a like hemorrhage, which came on about 7 P.M., daily, and continued until the sixth day, in spite of the efforts of the attending physician to control it. The patient having reached home, Dr. Robinson was called and made an examination with speculum. He found the os granular, denuded of its mucous coat, and upon gently opening the os with uterine dilators, he discovered a small clot adherent to the ulcer, which caused bleeding when removed. He applied carbolic acid to the ulcer and dusted the os and vagina with boric acid. He continued treatment until the parts were in a healthy condition and delivered the woman at full term, without hemorrhage, tear, or any unusual sequela. No placenta previa existed, and not one drop of blood escaped after the first application of carbolic acid until after delivery, and then everything was normal.

The second case occurred a few weeks subsequent to the first, with history and result similar.

He has for several years made it a practice to examine his regular patients whenever a yellowish or dirty white vaginal discharge exists, especially if the vulva is in a state of irritation, and almost invariably finds the os granulated, whether lacerated or not, and he persistently treats them until restored to a healthy condition, explaining fully to the patient the importance of such treatment.

DR. BEDFORD BROWN, of Alexandria, Va., corroborated the statements of Dr. Robinson by the relation of a case. The patient had a bilateral laceration of the cervix. She became bitterly hostile to sexual intercourse with her husband, and had an intense dislike of his company and presence. This preyed upon her mind to such an extent that she became insane. He treated the case with applications of nitrate of silver, and the lacerations healed perfectly. After this all symptoms entirely disappeared. The patient regained her reason, her affection for her husband, and lost the hostility to sexual intercourse which she had had. She has since borne three children. Dr. Brown has examined the condition of the cervix after each birth, and the repair is perfect.

The paper was further discussed by DR. RICHARD DOUGLAS, of Nashville.

EVENING SESSION.

The Association met in Broad Street Museum Hall at 8 P. M. The Address of Welcome was delivered by Hon. A. J. Caldwell, the response to which was made by Dr. J. M. Mathews, of Louisville. Dr. Hunter McGuire then delivered the Presidential Address, which was scholarly, timely, and well received.

(To be continued.)

Book Reviews.

THE EVIL THAT HAS BEEN SAID OF DOCTORS; Extracts from Early Writers, Collated from "*Le mal qu'on a dit des Medicines*" of Dr. S. J. Witkowski. Translated with annotations by T. C. MINOR, M.D. Pages, 136. Reprint from the *Lancet-Clinic*. Robert Clark & Co., publishers, Cincinnati, 1889.

No classes of men are more liable to be the objects of fulsome flattery or unwarrantable abuse than physicians. The limitations of human knowledge and the great responsibility incident to the practice of medicine is the obvious reason for this. At all times, literary men especially, have found in the medical art and science of their day an easy target at which to aim their shafts of wit and satire. The present volume is a compilation of such effusions taken from the literature of the early Greek and Latin, French and English nations, and will afford much amusement and instructive reading, even to physicians themselves. Many of the extracts are old and familiar, yet are good enough to be read again. The anecdotes and quotations added by the translator are no less creditable to Dr. Minor than the admirable manner of the translation itself. We urge our readers who desire a kind of medical relaxation to secure this interesting and suggestive little book.

Pamphlets.

Recent Advances in the Diagnosis and Treatment of Some Diseases of the Stomach, by L. Wolff, M.D., Physician to German Hospital of Philadelphia, etc. Reprint from the *Medical News*, September 21, 1889.

The Disposal of the Dead, by John M. Peacock, M.D., Brooklyn, N. Y. Reprint from the *Brooklyn Medical Journal*, August, 1889.

The Medical Digest.

Dr. Pattella, of Rome, has made some very important studies on the biology of the pneumococcus in relation to croupous pneumonia.

Extracting the pulmonic juice with a syringe always at the same spot, and making a culture of the active agent, he has been able to conclude that the lungs in passing from red to gray hepatization become a very unfavorable field for the vitality of the germs. The juice, according to the writer, becomes acid in the last stage of the disease, and this acidity kills the parasite, as he has proved experimentally.

To this is due the characteristic progress of pneumonia, the rapid abatement of all the symptoms, and the rapid defervescence.—*Riforma Medica.*

Dr. Voskresenski reports a case of a woman who was married four years and was anxious to bear children. There was no apparent cause for her sterility, as the husband was perfectly well and had a son by his previous wife, and the woman was also healthy. Dr. V. decided to examine the genitals of the male, and found that the penis in erection was curved considerably towards the left. Supposing that on account of this curvature the sperm was not in a position to reach directly the os-uteri or cervix, he advised the couple to assume the knee-elbow position in the act of copulation. In a month the woman became pregnant.—*Russkaya Medicina in Vratch.*

The Detection of Arsenic in the Bones.—Medico-legal investigations, having for object the detection of arsenic, generally bear on the stomach and liver, and, given the importance of the subject, some observations recently published in the *Revue Scientifique* bearing thereon possess an interest of their own. M. Pouchet has shown, by a series of carefully conducted experiments, that however administered during life, the poison accumulates in the spongy tissues of the bones, more particularly in the cranium and vertebræ. It may be detected there long after all trace has disappeared from the viscera. This localization is specially well-marked when the administration of the poison has been spread over a long period. When, on the contrary, the dose has been such as to determine a fatal result within a few hours, it should be sought for preferably in bones largely composed of compact tissue. Thus stored up, the poison is eliminated with extreme slowness, and may be isolated eight or ten weeks after the administration of the poison has been discontinued, whereas in the viscera only negative results are obtainable even as early as the third or fourth week. The tendency of arsenic to replace the phosphorus in bones has long been recognized, but it remained for M. Pouchet to call attention to the slowness with which the bones give up their accumulations, a point of great importance from a medico-legal point of view.—*Med. Press.*

Blood Pressure, Temperature, Pulse, Perspiration and Exhalation in Intermittent Fever.—The investigation of the above in forty cases conducted by Dr. V. N. Okunoff gave the following results:

1. Blood pressure falls at the beginning of the cold stage, and soon rises considerably above the normal.

2. In the last stage it is above the normal, but below that of the cold stage; then it gradually falls to the normal, and at times to below the normal.

3. In the perspiration stage it falls below the normal, at times considerably so.

4. The greatest number of pulse beats coincides with the last stage—consequently with the rise of blood pressure above the normal, but neither with the highest nor with the lowest points.

5. The frequency of respiration follows the course of the temperature.

6. The temperature in the axilla in the cold stage is above the normal; in the hot stage it reaches its maximum, and during the third stage it falls to normal.

7. The temperature in the rectum in the majority of cases is above that of the axilla, with the exception of the beginning of the cold stage when it is considerably lower.

8. Temperature of the chest and abdomen is normal, or below normal in the cold stage. In the hot stage it is above the normal, and during perspiration falls to normal.

9. The amount of excretion is lowered; during the hot stage it is increased, and in perspiration it reaches the maximum.—*Vratch.*

Dr. Golgi, of Pavia, in studying the plasmodium of Marchiafava and Celli, attributed to malarial fever, has come to the conclusion that the tertian type can be distinguished from the quartan, not only clinically, but also by the microscope.

He has seen that the period of development and the segmentation of the parasite differ considerably in the tertian and quartan types. The plasmodium in tertian also presents more active amœboid movements and produces prolongations called pseudopodia, which are not observed in the quartan type. Therefore, there are two parasites of the disease, as there are two normal types of the fever, the quotidian being, according to the author, a complex form of tertian or quartan type.—*Giornale Medico Del Ro. Esercito.*

Vaccination Against Tuberculosis.—M. Daremberg, of Mentone, has read a note to the Academy of Medicine, embodying the following propositions:

1. In all consumptive maladies, general reconstituants act by enabling the organism to resist the poisons formed in the stomach and bowels by abnormal fermentations.

2. The evolution of tuberculosis in guinea pigs and rabbits may be retarded long, by habituating them, little by little, to support the tubercular virus.

3. The tubercular virus is a poison which one can manage like mineral or organic poisons.

4. If, on the one hand, one can increase or lessen the toxicity; if, on the other, it is possible to augment the resistance of the organism to the action of the virus, it ensues naturally that following this idea up, one may find the point at which the virus is transformed into a protective vaccine.—*Journal d'Hygiene.*

Medical News and Miscellany.

ELKHART, Ind., has diphtheria.

WEISSPORT, Pa., has typhoid fever.

LOCK HAVEN suffers with ague, typhoid, and scarlatina.

EIGHT deaths from typhoid fever last week, and fifty-three from consumption in Philadelphia.

THE three children of a Jeanette family died of diphtheria in as many hours, recently.

BORDENTOWN, N. J., finds its drinking water, taken from the Delaware, unfit for use.

AMBER is said to be so plentiful in Southern Mexico that natives use it for building fires.

TYPHOID fever and diphtheria are now the leading complaints in many parts of the Lehigh Valley.

EASTON is pretty sure to have a hospital, now that her ladies have interested themselves in the project.

DR. N. C. JOBS, of Springfield, N. J., was accidently shot while starting on a hunting trip, and died.

DR. CHARLES WOLTERS was elected Resident Physician to the Philadelphia Hospital, Department for the Insane.

ABOUT 400,000,000 people use opium, while 750,000 are confirmed opium-eaters; and of these, 95,000 live in the United States.

THE Homœopathic Charity Ball is said to have been a failure in every respect; the attendance being small and the receipts light.

THE death is announced of Dr. Baierlacher, of Nürnberg, a well-known authority on electro-therapeutics, in his sixty-sixth year.

A CHILD of twelve years recently died of peritonitis induced by the swallowing of a pin, which subsequently became imbedded in the intestines.

DURING the voyage from Bremen of the steamship Fulda, four children among the steerage passengers died of diphtheria, and were buried at sea.

ONE of the best agents to abort a coryza, according to Dr. Beverley Robinson, is carbonate of ammonia, in frequently repeated and rather large doses.

DR. J. HOWARD PUGH has been appointed by the Supreme Court a member of the Board of Managers of the State Lunatic Asylum, located at Trenton.

SPENCER, Ind., owns a well whose waters magically promote hirsute growth, whether it be of the incipient mustache, or on the shining crown divested of its natural glory.

THE institutions to receive the receipts of the tenth annual charity ball, to be held in the Academy of Music on January 14, 1890, are the Sheltering Arms, the Polyclinic Hospital, the Philadelphia Lying-in Charity and Nurse School, and the Visiting Nurse Society of Philadelphia.

EXPERIMENTS at Leipsic show that skin grafted from a white to a colored person becomes gradually black, and that black skin grafted upon a white person in time becomes white.

THE London *Lancet* states that in the last thirteen years at least 120 deaths have occurred under chloroform, 59 of this number being before the operation, and thus clearly due to chloroform alone.

THE New York Board of Health has decided to resort to radical measures to rid the city of the stenches caused by the manufacture of gas. The Board is prepared to carry its case into the Courts.

Vaseline and water may be mixed by the addition of two drops of castor oil to each gramme of the liquid. By this means iodide of potassium may be introduced into an unguent without danger of decomposition.

THE Board of Health has entered a crusade against the Point Breeze refineries. It is claimed that the odors weaken vitality, and predispose the system to take any contagious disease that might settle upon the community.

SIXTEEN students of the St. Petersburg Military Academy of Medicine have been expelled from that institution for attending a Nihilist funeral. They are supposed to be implicated in a plot against his quaking Majesty.

DR. DUNCAN, physician of the steamer Colon, who while suffering with remittent fever last June was bundled off to Swinburne Island by the Brooklyn authorities as a yellow fever patient, has sued that city for $60,000 damages.

IT has been proved that heartbeats can be detected by electricity. The hands of a subject dipped into two basins of water in connection with a capillary electrometer, cause a deflection of the instrument at every beat of the pulse.

FRUITS, to do their best work as correctives for disordered digestion, should be eaten at the beginning of a meal, and not after oily foods—meats, vegetables, or high seasoning—when they become more of a curse than a blessing.

THIS has been a year of misfortune for Dr. Thomas Cooper, of Hatfield, Pa. First a valuable horse was stolen; next, eight hundred dollars in cash disappeared from his safe, and now his barn and drug store have just been destroyed by fire.

THE minor trust committee of the Board of Directors of City Trusts, directed that two handsome brass bedsteads be placed in the Wills Eye Hospital, in recognition of the bequests of Mrs. Hannah C. Flickwir and Miss Mary M. Calhoun.

THE MIDDLETON GOLDSMITH LECTURE.—Prof. William Pepper, Provost of the University of Pennsylvania, will deliver the Middleton Goldsmith Lecture before the New York Pathological Society, in the hall of the New York Academy of Medicine, on Wednesday evening, January 15, 1890. The subject of the lecture will be "Hepatic Fever."

Dr. Tyndale, of New York, was severely hurt by a drunken man, who took a catlin from the doctor and cut him with it. It is safe to say that the doctor will adopt the cowboy rule hereafter—never to put hand to weapon unless you mean to use it.

In Spitzka's Manual of Insanity the author recommends Squibb's fluid extract of conium, in doses of half a drachm, for violent maniacal excitement. This is a very large dose of this active agent, as death has followed the administration of forty minims.

We hear that a grateful patient recently presented to a church in Vienna a portrait of Billroth, representing him in the operating room. Why does not the grateful patient endow a chair—or at least a scholarship—in a medical college sometimes?"

A school for the thorough instruction of nurses in the care of babies is to be established in New York, in connection with the Babies' Hospital there. The *Herald* states that there is no school of the kind either in this country or in England, the only one in existence being in Germany.

An antiseptic ointment, certain in power and not unpleasant in odor, is often desired, not only by the obstetrician, but also by the gynæcologist. Dr. Th. Parvin says that benzoated lard, to which 4 per cent. of creolin is added, will meet these indications satisfactorily.—*College and Clinical Record.*

Dr. B. F. Shimwell is meeting with little encouragement in his efforts for the advancement of science. He has had a private hospital in which he has been studying surgery upon dogs; but the neighbors have complained of their howling as a nuisance. This is the fourth time he has been compelled to move. This is an ungrateful world.

Dr. Andrew J. Ourt, who has been Secretary of the Committee on Lunacy of the State Board of Public Charities since its formation in 1883, has resigned, and Dr. Henry M. Wetherill, Jr., Assistant Physician of the Pennsylvania Hospital for the insane, has been elected in his place. The new Secretary has had twelve years' experience in lunacy matters.

Dr. L. Webster Fox, who has just returned from England with his bride, daughter of the late Dr. Bickerton, a distinguished English surgeon, was given a complimentary dinner at the Union League by his professional friends. Those present were Drs. Ashton, Andrews, Shakespeare, Barton, Hearn, Alison, Ogden, Wirgman, Horwitz, Vanzant, Graham, Bates, Daland, Faught, Gruel, Drake, Campbell, Bradfield, Hulshizer, Hartzell, Graham, Krause, Jones and Freund.

The Board of Health of Philadelphia asks for $8200 to provide for the inspection of milk. It is proposed to distribute the desired amount as follows:

Chief Inspector of Milk	$1200
Three Assistant Inspectors	3000
Four Collectors	2000
For analysis of milk, etc.	2000
	$8200

If this sum be sufficient for a really efficient inspection of *all* milk offered for sale in the city, the appropriation ought to be made; but the amount appears to be too small for the purpose. But if the object be to provide for the making of intermittent "raids," which pick up an offender here and there while the great majority go on in their evil ways with impunity, we hope the measure will fail. In this case, the man who furnishes really good milk goes to bankruptcy; while the successful one, in a business point of view, is he who sells a poor article and is smart or lucky enough to escape detection. In fact, as history repeats itself, it is an illustration of the Spartan custom of honoring a thief, unless he gets caught.

To Contributors and Correspondents.

All articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Changes in the Medical Corps of the United States Navy for the week ending November 23, 1889.

Rush, W. H., Passed Assistant-Surgeon. Ordered to U. S. S Saratoga.

Urie, P. F., Assistant-Surgeon. From Coast Survey Str. Gedney, and to the U. S. S. New Hampshire.

Bryant, P. H., Assistant-Surgeon. From the Norfolk Hospital, and to the Coast Survey Str. Gedney.

Smith, Geo. T., Assistant-Surgeon. From the Army and Navy Hospital, Hot Springs, Ark., and to Naval Hospital, Norfolk, Va.

Stine, E. P., Assistant-Surgeon. After examination for promotion, await orders at Boston, Mass.

Official List of Changes of Stations and Duties of Medical Officers of the U.S. Marine Hospital Service for the three weeks ended November 9, 1889.

Purviance, George, Surgeon. Granted leave of absence for twenty-one days. November 8, 1889.

Austin, H. W., Surgeon. To inspect unserviceable property at St. Louis Marine Hospital. November 4, 1889.

Gassaway, J. M., Surgeon. Relieved from duty at New Orleans, La., to rejoin station at Cairo, Ill. October 23, 1889.

Banks, C. E., Passed Assistant-Surgeon. Granted leave of absence for thirty days. October 28, 1889.

Stoner. J. B., Assistant-Surgeon. Ordered to Vineyard Haven, Mass., for temporary duty. November 6, 1889.

Condict, A. W., Assistant-Surgeon. Ordered to Cairo, Ill., for temporary duty. Nov. 4, 1889.

Guiteras, G. M., Assistant-Surgeon. Ordered to Washington, D. C., for temporary duty. November 8, 1889.

Groenevelt, J. F., Assistant-Surgeon. Ordered to New York, N. Y., for temporary duty. November 5, 1889.

Clinical Lecture.

ILLUSTRATIVE OF SPINAL LOCALIZATION.[1]

BY CHARLES K. MILLS, M.D.,

Neurologist to the Philadelphia Hospital, Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic.

CORNUAL HEMORRHAGIC MYELITIS AT DIFFERENT LEVELS—PARALYSIS OF THE ARM FROM AFFECTION OF THE GRAY MATTER, AND OF THE LEG FROM EXTENSION TO THE PYRAMIDAL TRACTS—ATROPHIC PARALYSIS IN THE FACIAL AND TRIGEMINAL DISTRIBUTION.

SPINAL localization has long been a subject of great interest to the neurologist and neuro physiologist, and in very recent years its study has received a strong impetus from the fact that surgeons no longer hesitate to lay open the vertebral canal. Some of the cases which will be shown and studied in this and succeeding lectures, have a possible surgical importance; others have particular value for other reasons. In a broad sense, spinal localization includes a study of lesions focal or diffused, acute or chronic, vertical or horizontal; but I will limit myself in this course of lectures to focal lesions affecting the spinal column or cord at different heights, either by pressure, nerve involvement, or destruction of nuclei.

The first case to which your attention will be directed is one of unusual character, and, in my experience, very rare, and one also which, on superficial study, might be misleading. The various lesions in this case seem to have primarily involved certain groups of cells in the gray matter of the spinal cord and bulb, therefore giving an admirable opportunity of making a clinical study of the condition of the paralyzed muscles related to cell-clusters at particular locations transversely; but I will first give you a history and some details about the patient, and then study him before you.

The following are the notes of this case from the hospital records, but somewhat condensed;

W. S., aged fifty-three, born in Germany, in 1863, had a non-inflammatory bubo of the right side, and shortly afterward his hair fell out slightly, but he had no other secondary symptoms. He cannot remember having had any chancre. He had always been a moderate drinker. In 1869 he was disabled for several months by an attack of rheumatism.

In March, 1884, he had a sudden left hemiplegia or monoplegia without unconsciousness, for which he was admitted to the Philadelphia Hospital. Both arm and leg were involved in the palsy. In twelve weeks he was so far recovered as to be able to walk with the aid of a cane, and was discharged. In November, 1886, he had another apoplectiform seizure, with unconsciousness and delirium. This was not accompanied by palsy, and he rapidly recovered, being able in three weeks to walk without a cane.

In January, 1888, after a few days of headache, difficulty of speech, pain in the eyes, sensations of cold, he arose one morning with left facial palsy, which was almost complete. His mouth was drawn to the left when he came under observation, apparently from secondary contractions.

It has been recently discovered that this patient has also an affection of the muscles to which the motor branches of the fifth nerve are distributed, as well as

[1] Delivered at the Philadelphia Hospital, November 16, 1889.

of some of the sensory fibers of the same nerve. Some months ago he developed a serious anæsthetic and inflammatory affection of his left eye, and eventually this eye was removed by Dr. de Schweinitz.

A recent examination developed the following facts with reference to his face: "The left forehead is absolutely smooth, and the patient cannot corrugate it. The left angle of the mouth is drawn upward with rigidity and enlargement in the line of the naso-labial fold, probably due to a persistent spastic condition. Every few minutes the eyelids and muscles of the left side of the face twitch. He cannot fully protrude the tongue, but can just manage to get its tip to or beyond the under lip; tremulous, undulatory movements of the tongue are present usually. He cannot whistle nor dilate the left nostril. The left platysma movement is weakened. The masseter and the temporal muscles are evidently both atrophied and weak. He cannot protrude the lower jaw nor perform grinding movements. Sensation is blunted over the left side of the face. Degeneration reaction is present both in the muscles of the seventh and of the fifth nerves."

Examination of his left arm shows paralysis with marked atrophy, particularly in the extensor and supinator muscles, although perhaps not absolutely confined to them. Advanced degeneration reaction is present in the arm as in the face. He has a wrist drop similar to that which is observed in cases of lead palsy, only not affecting both sides.

As will be noticed, he drags the left leg decidedly in walking. Close examination shows impairment of power in the muscles, both of the thigh and leg, much as in a case of cerebral monoplegia or hemiplegia, the extensors and abductors suffering more than their antagonists. No atrophy is present as in the arm, and all the muscles respond both to faradism and galvanism, a striking difference between this limb and the upper extremity and face.

An ophthalmoscopic examination made in January, 1889, by Dr. G. E. de Schweinitz, gave the following result: The right eye has a round pupil; light reflex is preserved; a large oval optic disc with a dish-like, shallow excavation; the disc distinctly gray, arteries as compared with the veins smaller than normal. Spots of pigment could be seen on the anterior capsule of the lens indicating a former iritis. In the left eye the pupil is nearly occluded as the result of a former iritis, preventing any view of the fundus. Diagnosis, old iritis and incipient atrophy of the optic nerve. Since the date of this examination, while the patient was under the care of Dr. Lloyd, the left eye became much inflamed, the cornea ulcerated and sloughed, and the eye, as already stated, was removed by Dr. Schweinitz.

Examination for hearing by Dr. Lloyd, showed that with the tuning fork applied to the center of the forehead, the patient did not appear to hear it in either ear. When applied to the central incisor teeth he always heard it best in the left ear (affected side). This he did whether either or both ears were closed. This test was applied frequently, and always with the same result, and would seem to prove that his partial deafness was due to paralysis of the tensor tympani, rather than to affection of the auditory nerve.

A peculiarity of this case is that touching or handling the patient on the paralyzed side, either on leg, arm or face, causes him to wince, shrink or complain. The affected parts seem to be sensitive. Sometimes handling the paralyzed limbs will bring on involuntary shaking movements of the arm of the opposite side.

Let us now study still more closely this case. It is one of rarity and unusual interest. We have here a man palsied upon the left side of the body, face, arm and leg. We will commence our examination with the arm and leg, as these were the first attacked. He can lift and use his arm for various movements of the shoulder, proving that he has good control of the muscles of the shoulder and upper arm, including the deltoid, supra- and infra-spinati, trapezius and rhomboid. He can also flex strongly at the elbow, showing that the biceps, coraco-brachialis, and brachialis anticus are not paralyzed. Let us look below the elbow. You see he is scarcely able to move his hand, the little motion produced coming from the upper arm. Continuing, we discover that this man's arm is almost totally paralyzed below the elbow, almost totally escaping above. The extensors of the hand and wrist, the flexors of the same, but not completely, the extensor of the thumb, and the intrinsic muscles of the hand are all involved. He has a little supinating power; the supinator longus in fact seeming to be the only muscle below the elbow which has escaped. He is able to rotate the arm inwards and with difficulty outwards. On close examination we find that his triceps, latissimus dorsi, and possibly teres muscles are paretic. Comparing the two arms, you will notice at once how greatly this left arm is atrophied below the elbow. He has a decided unilateral wrist drop.

In a case of this kind it is very important to test the electrical conditions of the muscles, and we will now proceed to do this, examining first with the faradic battery, and commencing with the upper arm muscles. You see how perfectly the deltoid responds to the current, also the scapular muscles, coraco-brachialis, brachialis anticus and biceps. The triceps response is weak; at any rate we do not get the quick response as in the others. Proceeding now to the forearm and hand, we get no response from the extensors at all, a slight one from the supinator. The extensors are absolutely palsied and atrophied. The pronators respond somewhat to a strong current. Some of the flexors of the wrist, to a certain extent, respond, but those of the fingers do not. We shall test also with the galvanic battery, for the reason that in some cases although we find an absolute loss of reaction with the faradic battery, there will be some response to the galvanic, but here, as you see, there will be no response in the muscles which did not react to faradism. The muscles are so dead and degenerated that nothing is left to contract.

Let us next look at his left leg. We find here a different state of affairs. His leg is more paralyzed than his arm, that is, he has a more general loss of motor power in his leg. His leg presents the features of

an ordinary case of cerebral monoplegia, instead of the palsy being confined to definite muscles above or below the knee. The muscles all react to the faradic and galvanic currents.

The two conditions of the limbs presented for diagnosis are then: 1. An atrophic paralysis with degenerative reaction in the left forearm. 2. A paralysis, general, but not complete and not atrophic, in the entire left leg, with response to the electrical currents.

This case was at first regarded as one of hemiplegia from brain lesion, but it is impossible to explain any atrophic paralysis like that seen in this forearm by a cerebral lesion. What can it be then?

We know, or believe we do, the functions of every segment of the spinal cord, and we have them here exhibited in a tabular form from a paper of my own on spinal localization.

Let me repeat for you from this table the muscles whose functions are represented in four of these spinal segments, those of the lower cervical cord. They are as follows:

Sixth Cervical Segment.—Biceps, brachialis anticus, subscapular, pectoralis (clavicular part), serratus magnus, triceps, extensors of wrist and fingers, pronators.

Seventh Cervical Segment.—Triceps (long head), extensors of wrist and fingers, pronators of wrist, flexors of wrist, subscapular, pectoralis (costal part), serratus magnus, latissimus dorsi, teres major.

Eighth Cervical Segment.—Triceps (long head), flexors of wrist and fingers, intrinsic hand muscles.

First Dorsal Segment.—Extensors of thumb, intrinsic hand muscles, thenar and hypothenar muscles.

This patient has had either a hemorrhage or a hemorrhagic myelitis affecting the anterior horns of the cord on one side, the inflammation or hemorrhage extending into the lateral column—to the motor tracts of the same side. The attack was practically a form of anterior poliomyelitis, but it is a question whether it was an inflammation or a hemorrhagic inflammation, or a hemorrhage. His leg gives the phenomena of cerebral paralysis, and the condition is due not to a trophic lesion of the gray matter, but to a destructive interference with the cross pyramidal tracts with, perhaps, some secondary degeneration.

If we make a series of transverse sections through the cord at different heights, we get different sizes of the horns of the cord, as seen in this diagram, showing such section. From the third or fourth cervical to the second dorsal segment, the horns are very large, because they represent extensive muscular movements in the upper extremity. The cells are arranged in groups, four or five cell-clusters. These groups may be only in one section, or may continue through two or three sections of the cord. Thus, if we cut through the sixth, seventh and eight cervical segments and the first dorsal, and examine microscopically, we find some of the same groups of cells represented in two or more sections. Each one of these cell-groups is a physiological unit, and represents a muscular movement. Consequently we know that the movements which are destroyed in this man are referable to certain groups of those cells, and thus we are able to locate the injury to the cord. Certain types of paralysis have been erected, both of the upper and lower limbs. Thus there is an upper arm type of paralysis which includes the muscles which have here escaped in this patient. We have also a forearm type which includes the muscles here paralyzed.

In the seventh cervical segment of the cord, you will see by referring to the tabular statement, are cells representing the long head of the triceps, the extensors of the wrist and fingers, the pronators and flexors of the wrist, the latissimus dorsi, teres major, and the costal parts of the pectoral muscles—almost exactly those here involved. In the eighth cervical are again the triceps, the flexors of the wrist and fingers, and in addition the intrinsic muscles of the hand, also the thumb and thenar muscles.

The lesion of the cervical cord in this man certainly involve chiefly the groups in these three segments; to some extent also the sixth segment. The probabilities are that the hemorrhage, or the focus of the myelitis, in this man was in the anterior horn of the left side in the seventh cervical segment, and that it reached out to the adjoining segments, and also to the white matter of the crossed pyramidal tracts.

Let us finally look at this man's face. He can wrinkle his forehead on the right side, but not on the left. He has a loss of power in the zygomatics, the orbicularis palpebrarum, and all the muscles about the mouth, showing a paralysis of the portio dura or seventh nerve. The temporal muscles on the left side, and the masseter and pterygoids are also paralyzed—an unusual condition. The electrical reaction of the face is the reaction of degeneration. This palsy occurred from the second attack.

As we ascend higher in the cord to the floor of the ventricle, we find large groups of cells which are the nuclei of the cranial muscles. Our patient has a paralysis of the facial nerve, and of the motor fifth. There is also some hyperæsthesia of the face. It is most likely that the same sort of lesion is present in the bulb as in the cord, a hemorrhagic or myelitis destroying cell-groups of both the facial and trigeminal nerves.

The disease of his eye, which led to removal, was not due to the fact that the eye was open as a result of the paralysis of the orbicularis palpebrarum, but was a trophic affection from the lesion of the nucleus of the fifth nerve.

A NEW skin disease among cattle in Maryland, Pennsylvania, Delaware and Virginia has recently come under the observation of Dr. Wray, State Veterinary Surgeon of Maryland. The first case was discovered in St. Mary's county in July last, and investigation showed that the disease is prevalent throughout this and adjoining States. The disease is not contagious, but arises spontaneously. The animal at first suffers from constipation, which is followed by sloughing and ulceration of the skin, particularly of the mouth, nose, etc. The disease does not seem to be fatal, but it interferes very much with the milking of cows afflicted with it.

FERMENTATION—ITS CAUSE AND EFFECTS.[1]

By ERNEST LAPLACE, A.M., M.D., Paris,
Professor of Pathology in the Medico-Chirurgical College, Philadelphia.

GENTLEMEN:—All that lives must die, and, dying, disintegrate and resolve itself into elements that enter into new cycles of usefulness. This phenomenon of universal disintegration must have aroused the interest of the human intellect from the first moment that it reached such a state of perfection as led it to inquire into the causes of things. If this disintegration did not exist, the matter of organized beings would encumber the earth, and the law of perpetuity of life would be compromised. A great phenomenon presides over this work; this phenomenon is fermentation.

Our forefathers might have been savages, but they were clever and observant ones. After organizing their own rude arts, they turned beasts into servants, they founded agriculture, planted the grape—this fruit was surely antediluvian, for we are told that Noah, on leaving the ark, planted a vineyard, drank of the wine, and experienced its consequences. But though wine and beer are as old as history, it was not until the last few decades that anything positive has been known as to the true mode of their formation. Our knowledge in the matter has been almost identical with our knowledge of medicine, that is, empirical—by which is meant that we had observed the facts, aside from the principles which produce them, and which are essential for a true understanding of them. In a word, when light dawned upon the true secret of the manufacture of beer, by the immortal discoveries of Pasteur, that same beam spread itself over the whole realm of medicine; was the light of regeneration to the noblest of sciences.

The brewer learned from long experience the conditions, not the reasons, of success. Often, however, the brewer's beer has fallen into rottenness, without any accountable cause.

It is the hidden enemies against which the physician—like the brewer—has had to contend, that recent researches are dragging into the light of day, thus preparing the way for their final extermination.

While still a young man, Pasteur, who was then a professor of chemistry in the Ecole Normale of Paris, was attracted by a note of the German chemist Mitscherlich, in which he said to the Academy of Sciences: "The tartrate and paratartrate of soda and ammonium have the same chemical composition, the same crystalline form and angles, the same specific weight, and the same double refraction. Dissolved in water, the refraction is the same. But the dissolved tartrate turns the ray of polarized light to the left, whereas the paratartrate is *indifferent*. But," adds Mitscherlich, "the nature and the number of the atoms is identically the same." Pasteur, who was then but twenty-five years of age, discovered that the crystals which turned polarized light, were not symmetrical. He noticed that all products of organic life were dissymmetrical—such as starch, quinine, strychnine, while all mineral crystals, or products of the inorganic world, were symmetrical. He immediately suspected that tartrates were organic, that is, connected directly or indirectly with life. It was a well-known fact that a German manufacturer of chemical products, having thrown away some impure tartrate of lime, mixed with albuminoid materials, this had fermented, giving rise to different products. Pasteur reproduced this fermentation in the following way: Taking some tartaric acid, he added a certain amount of albuminous material, and placed it in an incubator. When fermentation had taken place, Pasteur found innumerable small living organisms, and after the process had stopped he polarized the liquid and found that, whereas before fermentation the polarization was to the left, it had now turned to the right. His suspicion was realized. Hence, this sudden change of the direction of the ray of polarized light was accompanied by a great development of living organisms during a process heretofore known simply as fermentation. This was the first hint ever gotten of the influence of a living micro-organism upon organic substances. This micro-organism was not present, apparently, when the mixture was placed in the incubator, and now it existed in swarms in the disintegrating mixture. They surely grew during the fermentation.

Up to this time the most incomplete notions had been entertained as to the true cause of fermentation. *Liebig* said they were "acidations of albuminous substances when in contact with air." *Gay-Lussac* thought that the oxygen of the air was the causative agent, for he had noticed that wine had turned sour from being poured from one vessel to another. Berzelius and Mitscherlich said that ferments acted by catalysis—that is, by their presence. Schwann and Cagnard Latour noticed that a living, rounded body was present in the manufacture of beer; but it did not occur to them to ascertain what part was played by this organism. As soon as the malt is mixed with hops it is boiled, and allowed to cool; this infusion is called the wort, and this is placed in vessels with but one aperture open to the air. Here it is mixed with the yeast. Soon after a brown froth forms on the surface, which is really new yeast, and issues from the aperture, falling like a cataract into troughs prepared to receive it. Whence is this new yeast? Weigh it before and after. The brewer sows ten pounds and he collects fifty pounds. Shall we say that this is spontaneous? Are we not reminded of the seed that has fallen in good soil and brought forth fruit fifty- or a hundred-fold? In fact, this seed can be seen budding under the microscope, before our own eyes. It is a minute plant—the Torula Cerevisiæ. This marks a distinct epoch in the history of fermentation. But Liebig was loath to accept the growth of this plant as the cause of fermentation, and maintained that its life had nothing to do with the process, that it was a purely chemical one, and that it was the chemical nature of yeast, not the fact that it was alive and could develop life,

[1] Delivered before the Odontological Society of Pennsylvania, November 2, 1889.

which produced fermentation. In a memorable demonstration, Ludersdorf proved the error of Liebig's assertion, and that yeast acted as a ferment because of its organized or living character.

He destroyed the cells of yeast by rubbing them on a ground glass plate, and he found that with the destruction of the organism, the chemical nature remaining the same, the power to act as a ferment disappeared totally. No experiment could possibly be more conclusive.

But in the manufacture of wine, no yeast is added. The grape is pressed, and the juice ferments after a short while. The torula soon makes its appearance, however, and where does it come from? If the filtered grape juice be boiled, so as to destroy the germs it contains, and be put in germless air, it will never ferment. All the material for spontaneous generation is there, but the life, both in the grape juice and the air, being destroyed, no new life can be produced in the shape of fermentation.

Pasteur has pushed this demonstration still further. The grape is sealed by its own skin from contamination by the air. He contrived a way of extracting the juice, without its touching any contaminated substance, and placing it in pure air; it did not ferment; then taking the skin of the grape and brushing the delicate grayish dust upon this non fermenting juice, fermentation soon developed and the yeast plant appeared in great abundance, proving that the grape carries its yeast upon its own self. For thousands of years, therefore, the wine grower has done unconsciously what the brewer does purposely.

The germ of the yeast plant exists in the air, but not in quantities sufficient to ensure rapid fermentation such as the brewer desires, hence the brewer puts in a quantity himself.

Pasteur has defined fermentation as life without air. These germs live on oxygen as we do, and give off carbonic acid gas; but they do not take their oxygen from the air, they take it from the substance upon which they grow, hence they do not need the oxygen of the air for their development. Hence fermenting substances are placed in vessels with but a small aperture to the open air, where the yeast imbibes oxygen and pours forth carbonic acid. Where does it get the oxygen? It is wrenched from the liquid upon which it grows, liberates carbonic acid gas, and leaves the liquid product as our familiar alcohol.

And in the same way, exposing alcohol to the action of the ferment known as the mycoderma aceti, acetic acid will be the result.

The air is full of germs of ferments differing from the alcoholic leaven. Expose milk to the air and the coagulation will take place; small globules of butter appear—the butyric acid fermentation. Within a short while larger organisms are seen, wriggling in swarms through the preparation. In curdled milk are found other organisms, linked together as beads on a string—that is the *lactic acid fermentation*. Examine putrefying milk and it will be seen to swarm with millions of small and larger germs, showing wonderful alacrity of motion. Keep your milk from the influence of the atmosphere, or boil it, so as to kill the germs within it, and it will remain sweet, the germs being destroyed.

Expose meat to the atmosphere and it will soon putrefy; it will swarm with the germs of putrefaction and will soon stink. Keep the germs away and it will not putrefy.

Thus we begin to see that within the world of life to which we ourselves belong there is another world requiring the microscope for its discernment; but which, nevertheless, has a most important bearing upon our welfare.

Gathering these facts together and analysing them, we see that there are two elements always in action—a seed and a soil. The seeds are floating continually in the atmosphere about us. The soil is the particular substance upon which these germs fall, and at the expense of which they grow. It follows, also, that the greatest analogy exists between these various germs in the atmosphere and the seeds of various plants that may be wafted by the wind from one spot to another, and which develop when they happen to fall upon a suited soil.

Another fact is, that just as when you sow corn corn is reaped and not barley, so each particular germ grows its particular kind. Supposing you take a handful of seeds of various flowers and sow them in the same soil, then the different plants will grow alongside of one another. So also, if various sorts of germs have access to the same soil, they may grow plentifully together—as takes place in putrefaction, where germs of many kinds are seen growing, and decomposing the soil upon which they grow, liberating, not carbonic acid—as in fermentation—but sulphuretted hydrogen, the foul smell of putrefaction.

All germs will not grow on the same soil, just as all seeds will not grow on the same ground—some plants being indigenous to some countries, and others to different climates.

But a very astonishing fact is that one germ, after developing in a particular soil, may leave that soil in such a state as will render it favorable to the development of a germ which could not have developed there before. Such is indeed the case with the mycoderma aceti, which could not have developed in the sweet solution. First the yeast plant developed there, changing the sugar into alcohol, and now the mycoderma aceti, falling into the alcohol grows abundantly, changing this alcohol into acetic acid, or vinegar.

The most important and practical portion of the whole knowledge of the nature and development of micro-organisms is the study of the changes incident to their growth in the soil upon which they develop. The yeast plant left the sugar changed into alcohol, whose chemical nature and physiological effects are quite different from sugar. The mycoderma aceti has changed the alcohol into vinegar, whose chemical nature and physiological effects are vastly different from alcohol. Likewise the lactic acid germ has produced in milk which was once sweet a substance, lactic acid, having corrosive properties, and which curdles the milk.

This new product, which results from the decom-

position incident to the development of a germ, is called in medicine a ptomaine. When germs are absorbed from the atmosphere and produce certain diseases, the albuminoids are decomposed within us, and this ptomaine or fermentative product is the chemical poison formed, which, being resorbed by the economy, produces those physiological symptoms characteristic of a disease.

And would a substance not putrefy without the action of germs?—in other words, is there such a thing as spontaneous generation? Tyndall's and Pasteur's admirable researches have set this question at rest. One will suffice. Having made veal broth, Pasteur placed it in a round vessel with but a small aperture. This was raised to a temperature of 115° C. for half an hour, so as to destroy all the germs within it, and the tip end of the flask was soldered, so as to prevent further air from coming in contact with the broth. A number of flasks so treated were placed aside. I have one in my possession thus prepared many years ago by Pasteur himself, and the contents are as pure as the day of its preparation. This shows conclusively that by heat he had sterilized the liquid and interior of the flask, and having soldered the end of the flask, thus preventing any germs of the atmosphere from having access to the fluid, there was no possibility of life developing within it; hence it remains pure, and is likely to remain pure indefinitely.

Now this simple experiment was a master-stroke of genius, for on it is founded our whole system of modern pathology and hygiene.

Do we wish to stop fermentation, putrefaction, contagious and epidemic diseases? We must repeat Pasteur's experiment. Sterilize first. Then prevent the germs from having further access to the parts thus purified.

Strange to say, this process of purification was applied to the canning of goods before it was practically applied to scientific purposes. In fact, canned goods of all sorts are prepared exactly after the manner of Pasteur's broth-experiment. They are raised to high temperature and kept in air-tight vessels. And what occurs when canned goods become spoiled? Simply the germs of the air have gotten into the goods, whether through some small aperture in the vessel or sufficient heat was not applied at first to destroy them.

Lister, in England, was the first to make a practical application of this to suppuration in wounds. He saw the analogy between the foul smell of a suppurating wound and the processes of putrefaction, and concluded that, should he succeed in destroying the germs which had started this putrefying process, and should he prevent further germs from having access to the wound, the putrefaction would cease, and the wound would heal kindly without suppuration. This he did by sterilizing the wound.

There are two ways of sterilizing: by (1) heat; (2) by chemical agents, carbolic acid, sublimate, etc., which have the property of destroying the vitality of most micro-organisms; and, when used in proper strength, do so without impairing the tissues with which they come in contact. The wound is then covered with several layers of cotton that has been sterilized or purified by heat, and this prevents the germs of the air from having further access to the wound; for as these germs fall upon the outer layers of the cotton they are caught by the meshes of the small cotton fibres and are not allowed to get any nearer the wound; during this time the normal and unimpeded process of repair goes on, and healing takes place without suppuration or putrefaction produced by germs. And by this glorious discovery Lister has blessed humanity with a reduction in mortality from major surgical operations, a mortality reduced from fifty per cent. before the days of antisepsis to two or three per cent. at the present day in the best conducted hospitals. Besides, it has widened the domain of surgery, bringing to the surgeon success in such operations in which he could not hope for success should suppuration take place.

Applying the same principles to dental surgery, which is a special branch of general surgery, we are struck by the frequency of processes of putrefaction or fermentation in the mouth. And why? Because the germs of the atmosphere, which we constantly breathe through the mouth, lodge upon some remnant of food buried in the sulci, fissures and proximal surfaces of the teeth, and find there a suited soil accompanied by heat and moisture; these germs develop and cause putrefaction, as evidenced by the foul odors from the mouth. Besides putrefactive processes, a fermentative process may also take place in the presence of sugar, which produces a corrosive element that destroys the enamel. The germs sink into this impaired spot, and the same deleterious agent being generated there, the process of decay attacks the dentine, the pulp, and an extensive cavity follows. Such being the case for a healthy tooth, well paved with enamel, the process is a much easier and more rapid one when, through some accident, a mechanical abrasion already exists.

To the honor and credit of Prof. W. D. Miller, of Berlin, be it said that he was the first to discover that the corrosive substance so deleterious to enamel, and which results from fermentation in the mouth, was lactic acid, which enters into composition with the calcium salts of the tooth, producing a lactate of lime.

This being the case, as a student of pathology and practitioner in surgery I conjure you to apply to your special branch of surgery the principles of antisepsis that Lister has applied to general surgery, vouching that you will meet the same grand success.

To reach this end, sterilize! and prevent the further access of germs to the parts. Sterilize with acid sublimate solution, destroying the organisms at one sitting. But when the pulp is dead, use the heated platinum broach in the root canals; then use the antiseptic solution, which will penetrate the minutest nooks of the cavity and destroy those few germs that have perhaps escaped the heat. Finally, plug the tooth with aseptic or antiseptic filling. And, gentlemen, as a physician, knowing how many general disorders, gastric and others, are caused by germs that found originally a brooding place in the mouth, I implore you to give the question of oral disin-

fection your most scrupulous attention, feeling confident that a rational and persistent use of the antiseptic solutions now within our reach will afford you the fullest satisfaction, for in your treatment you will meet the same glorious success as is achieved in surgery as practised at your doors.

* * * And now, that we have reviewed the various phenomena of fermentation, we see that, in the eternal laws of the universe, that fermentation was destined as a power for good, and like electricity and steam, it vastly benefits our existence, if only rightly understood and maintained within its proper bounds; that most of the harm to humanity resulting from fermentative processes is due to our still incomplete mastery of its laws; and that, with the present strides of science, we will completely overcome these micro-organisms or fermentative agents that are deleterious to man and his surroundings.

Such is the triumph of the scientific age in which we live, that has disclosed a world about us which we know not of—a world of beings consisting of enemies as well as benefactors, in constant and intimate relation with each of us.

We know of numberless stars above, infinitely large; but this newly-discovered world of infinitely small beings, its laws and purposes, is to me not a lesser index to that Power, the Author of them all.

That God which ever lives and loves.
One God, one law, one element,
And one far-off divine event,
To which the whole creation moves.

CRIMINAL RESPONSIBILITY IN NARCOMANIA.[1]

BY NORMAN KERR, M.D., F.L.S.,
President of the Society for the Study of Inebriety; Corres. Mem. Medico-Legal Society; Chairman British Medical Association Inebriates' Legislation Committee; Fellow of the Medical Society of London.

IN some countries, as in Germany, Italy or Switzerland, there is a difference in the penalties inflicted by the law for crimes committed in a state of inculpable, as distinguished from culpable, intoxication. In most countries, as in America, England and France, the law does not officially recognize such a distinction. There have been occasions when English judges have even gone so far as to declare, following the ruling of the Spartan lawgivers, that drunkenness is an aggravation of the criminal act, and ought to call down additional punishment.

But the comparatively recent revelation of medical scientific research that there is often a diseased condition of the brain in individuals guilty of either a sudden and unexpected outrage of the laws of decency or morality (or of a continuance of such outrages), while affected by alcohol or some other anæsthetic, has not been without influence on the administrators of justice. Jurisprudence was constructed at a period when no abnormal physical state in inebriety was suspected, except, by perhaps a few rare scientific inquirers, who were far in advance of their day and generation. Scattered here and there in the annals of English criminal procedure are deliverances from the judicial bench, as well as verdicts, which attest the growing influence of the discoveries of pathology and physiology on the humane, more merciful and withal just legal treatment of the diseased inebriate.

In one case, two men were going home from a public house drunk. It was believed that the one as a joke tried to rob the other. But the prisoner was held to have been under the delusion that he was attacked in earnest by a real thief, and though he killed his friend, was acquitted. The judge said that the accused had clearly acted under the impression that his life was in danger, and under these circumstances could not be held to be criminal (*Reg. v. Price*, Maidstone Summer Assizes, 1846).

This ruling would cover a large number of accusations for capital and non-capital offences. It would include many crimes committed during an attack of delirium tremens, for example. All the injuries to persons inflicted by the alcoholic trembling deliriate, which have come under my notice have been the act of a person under the delusion that his life or liberty was at stake. He believed that some one was after him, was trying to rob, maim, imprison or kill him, and in his terror he violently assaulted his presumed assailant. In other cases, he has injured persons unintentionally by clutching at them or clinging to them in the acme of his fear.

On one occasion, at sea, I had a very narrow escape from strangulation at the hands of a man suffering from delirium tremens. As I was about to leave his cabin, he was so afraid of my leaving him that he, while my attention was diverted from him for a second, had my trachea compressed by one arm in an iron grip of despair and frenzy (I being jammed up in a corner) with his other hand rigid on the door handle. I was helpless and voiceless. Nothing saved me from impending death but the being able to control him by my look, with the consequent relaxation of his grasp, when I at once opened the door.

There have been a number of acquittals in charges of murder during delirium tremens. One of the most notable of these was the case of *Reg. v. Burns* (Liverpool Summer Assizes, 1865). The accused had murdered his wife. After the commission of this deed he appeared quite calm, and stated that he knew what he had done. His reason for killing his wife was that she was in league with men concealed in the walls. The jury acquitted the prisoner, on the ground laid down by Baron Bramwell that, though the accused might have known that the act was killing and was wrong, he was laboring under a delusion which led him to suppose that this delusion, if true, would have justified his action.

Another person was acquitted of feloniously wounding two individuals, on the plea that he was under the impression (from delirium tremens) that his house was being broken into (*Reg. v. Chaplin*, Warwick Assizes, November, 1878).

Yet, under almost similar circumstances, the accused have been found guilty, as in the following case: One man killed his friend, both being drunk, under the delusion that his friend was some one else, who was attacking him (*Reg. v. Paterson*, Norfolk Dent Assizes, 1840).

[1] Read before International Congress of Medico-Legal Societies.

Mr. Justice Manistry, in *Reg. v. McGowan* (Manch. Assizes, October, 1878), where a man was found guilty of murdering his wife, though the medical evidence was to the effect that he was laboring under temporary disease of the brain from excessive drinking, ruled that disease produced by one's own act, such as delirium tremens, was no excuse unless the disease became permanent.

On the whole, though the plea has in some cases been unavailing to avert condemnation, there has of late years been an increasing disposition in both judge and jury to accept a delusion of delirium tremens as a valid ground of acquittal. This is undoubtedly a step in the right direction. In some cases, the accused may not be wholly unconscious of the nature of the act, or of the difference between right and wrong; but he is beyond his own control, and is powerless to resist the dominating homicidal or suicidal impulse even in this partial consciousness of his actions. This delirium is as pronounced a disease (however short lived) of the brain as is the delirium of typhus or typhoid fever. There ought to be no more criminal responsibility in the one disease than in either of the others.

It seems to me that on this point most legal and medical experts will be agreed. A uniform ruling to this effect would be an enormous gain to the successful administration of our criminal law. No drinker desires or intends to have delirium tremens. This disease (a leading characteristic of which is abject terror) overtakes him and comes upon him unawares.

To only one more point of medico-legal interest will I allude: viz., to the desirability, in fact the necessity, if justice is to be done, of an inquiry into the health history of the accused. Though I treat specially of criminal cases complicated with inebriety, this procedure would often be judicious when there is no narcotic complication.

A sober, sedate, conscientious and well living man or woman suddenly commits some gross breach of decency or order—is guilty, say, of indecent conduct, or of theft—without an apparent motive. In not a few cases which I have seen (in some of these cases no criminal proceedings were taken, in others there was a conviction or a reprimand) the immoral act, the theft, or the unexpected drunken outbreak proved to be the first symptom of paralysis of the brain. What a terrible blunder to punish such a person as an ordinary criminal! The disgrace, the prison surroundings, the jail curriculum, have degraded the *morale*, often made a confirmed criminal of the convicted, and accelerated the paralytic's march to the grave, the existence of an underlying disease having never been suspected until the incurable stage had been reached.

Such a neglect to inquire into the past health of the accused has often been as dishonoring to law and as costly a mistake to the community as it has been fatal to the individual. A more enlightened procedure would have detected and recognized the presence of brain disorder in a considerable proportion of cases. The result would have been that, though there would have been fewer convictions for crime, many persons would have been preserved from a criminal career, the heavy expenses incurred for not a few habitual criminals would have been saved, a large amount of brain disease might in its earlier and more curable stages have been cured, and quite a host of useful lives might have been restored to the community, while the dignity, power and influence of the law would have been greatly enhanced.

All these considerations apply with added force to the urgent need for an elucidation of the HEREDITY of the accused. Especially where inebriety is present should the family history be sought out. There are many individuals so handicapped, so permeated with the alcoholic or other inebriate inheritance transmitted from their predecessors, that the slightest sip on any pretence of an alcoholic intoxicant is apt to precipitate them into intoxication, with the risk of *incontinently and not of their own intent* being guilty of some criminal offence while under the influence of the anæsthetic. There are others born with a brain so abnormal that the drink-impulse or the drink-crave is apt to be developed by any extraordinary disturbance or exhaustion of their nerve system. There are still others whose moral control is so deficient from birth that only with the greatest difficulty can they resist temptations from without or morbid impulses from within.

I am glad to be able to adduce a recent deliverance from the English bench in illustration of the importance of giving due consideration to heredity, in a case with inebriate complication. (*Reg. v. Mountain*, Leeds Assizes, 1888.)

A single man, aged thirty-four, was tried for murdering his mother with prolonged violence, in the presence of a terrified domestic whom he had locked up in a room with them all night. He had suffered from delirium tremens about five years before, and for the last year had been subject to fits of excitement, and to delusions as to his life being threatened. He persisted in the statement that the victim was not his mother. One medical witness testified that at the time when the deed was done the perpetrator was suffering from *delirium tremens*, the other that the illness was *mania a potu*. Evidence was given showing an insane heredity. The judge, Baron Pollock, said that though no man could be excused on the mere plea that he had reduced himself to a want of reason by drinking, there were other circumstances here. One was that through hereditary influence the accused's infirmity and mental deterioration possibly did largely account for the criminal act. Another circumstance was whether, apart from drinking, the man was the subject of delusional insanity. The judge very wisely met the objection that if the prisoner had been an abstainer from alcoholic drink, he would not have been guilty of matricide; that as a certain amount of alcohol, with his predisposition, made him a murderer, the accused should not have taken the little drop that upset his reason. Baron Pollock replied that the last man to know his own weakness is he who has a weak mind; that such an one cannot argue as doctors argue for him. The learned judge charged that if, at the time when the murder was committed (though the accused had been a drunkard and had had delirium tremens) he had

taken only such a quantity of liquor as an ordinary man could take without upsetting his reason; and that the insane predisposition was the main factor, although the drinking of a small amount of alcohol was a contributory cause, the plea of irresponsibility, on the ground of insanity, was good. Happily, the jury returned a verdict in accordance with the charge of the judge.

In insanity it is now generally conceded that there is a lesion of the brain, though this cannot always be detected on a *post mortem* examination. There is now as much evidence to show that there is a brain lesion in inebriety, that diseased condition which I have ventured to call narcomania (a mania for intoxication by any anæsthetic narcotic). In acute mania, as in delirium tremens, this lesion is usually quickly repaired. In some forms of mental unsoundness and of narcomania, this lesion is so persistent that a prolonged course of treatment is required, while in a sensible proportion of cases the lesion is practically irreparable.

In the interests of justice, as well as in fairness to the accused, in all cases of alleged criminal offences committed either while under the influence of an alcoholic or other anæsthetic, or by a known inebriate in a non-narcotic interval, there ought to be a skilled inquiry into the previous health history and heredity of the panel at the bar.

Hydrotherapeutics.

A PLEA FOR THE PRACTICAL UTILIZATION OF HYDROTHERAPY.[1]

By SIMON BARUCH, M.D.,

Attending Physician New York Juvenile Asylum and Manhattan General Hospital.

(Continued from page 731)

THE question I now propose to discuss is "Why has the remedial use of water maintained its hold upon some of the most able physicians in every century of medical history, despite the prejudices of the lay and medical public?"

Why have the vicissitudes of hydrotherapy not swept it from the therapeutic field, as has been the fate of many more highly vaunted remedies? Bloodletting, that remedy which for centuries towered above all others and promised to resist the onslaught of its ablest opponents, is an example of the fate of a remedy which lost its foothold so soon as the fierce light of modern physiological research exposed the fallacious reasoning on which it was based.

Hydrotherapy, on the contrary, has maintained its position not only on clinical grounds, but it is to-day more firmly entrenched *because it is based upon well ascertained and exact physiological facts*, the application of which forms the most brilliant chapter of clinical medicine.

The more fiercely the light of modern research bears upon it, the more glaring become its points of vantage over many other remedies, *which, however, it should never be permitted to entirely displace.*

To demonstrate the validity of this claim, there is a wealth of material at my disposal, from which you will permit me to select a few striking evidences. The works of Winternitz, Schueller, Roehrig, Naumann, Chapman, Delmas, Thennes, Pleniger, Bottey, Scheuer and others, from which I am greatly indebted, teem with experiments on animals and man which must prove to the unbiased observer that by means of the thermic and mechanical effects of water prompt and decided modification may be impressed on all the functions of the body. Let us take, for instance, the most simple experiment of applying cold water to the skin. May we not arouse a patient thus from syncope? May we not modify tactile sensation to any extent, from the mildest effect to complete abeyance? May we not diminish the caliber of bloodvessels to any extent by cold, until their coats lose their tone altogether, or until they are dilated again by reaction?

Surely these effects and many others can be so positively controlled by no medicinal agent. We have physiological grounds, not alone for these, but for many other effects.

Naumann has by experiments on frogs established such definite results on the subject of the action of cutaneous stimuli that Winternitz accepts them as laws. He separated the head of a frog from his body, leaving them connected only by the medulla; he also severed one leg, after preventing loss of blood by tying the vessels, so as to leave it connected only by the sciatic nerve. He now applied thermal and other stimuli to the foot of the partially severed leg, while he observed the circulation of the mesentery under the microscope. Having observed certain changes in the latter, he formulated them as follows:

1. The effect of irritants is produced by reflex action from the central organ.

2. These irritants exert considerable influence on the heart and vessels.

3. In proportion to the irritability of the individual, powerful cutaneous stimuli lessen and weaken cardiac action, dilating the vessels.

4. Relatively weak stimulation increases and strengthens cardiac action and narrows the vessels.

5. The changes produced by long-continued skin stimulation last some time; longer if stimulation has been prolonged: even one-half to three-quarters of an hour beyond time of stimulation.

6. Relaxation of pulse following powerful stimulation of the skin often attains its maximum at once; at other times not until its conclusion.

7. The excitant effect of weak cutaneous stimulation continues after its conclusion; but it is also followed by a less pronounced relaxation.

8. Powerful cutaneous stimulation is always followed, after a period of warming, by a cooling down of the body, which lasts often over an hour, sometimes occurring during the stimulation, but as a rule after its cessation.

Schueller's observations on the circulation of the pia mater of a rabbit, which he had trephined for the purpose, are definite and unimpeachable, and explain

[1] Read before the New York Academy of Medicine, November 7, 1889.

many of the hydrotherapeutic processes. A cold stream of water applied to the belly and back of the rabbit was at once responded to by the bloodvessels of the pia mater, contracting them if brief, dilating them if prolonged. A warm compress applied to the belly contracted the vessels. Cold baths produced dilatations of the vessels in proportion to the size of the body immersed. Only, after prolonged immersion in cold water, a contraction of the vessels ensued as the result of the reduced blood temperature. The vessels continued contracted for about half an hour. If the body of the rabbit was immersed in warm water, a decided contraction of the vessels in the pia mater ensued, and they remained somewhat contracted for some time. His experiments with the cold pack on rabbits agree with the effect of these applications on man.

These experiments have been verified in man by Tranck, who in Marcy's laboratory, by means of self-registering instruments of precision has demonstrated that, if one hand be placed in cold water for two or three seconds, the other increases in volume, the increase continuing about a minute. Winternitz also verified Schueller's experiment on man by measuring the size of the arm by a pletysmograph, while the patient sat in a tub, receiving a cold affusion. The effect was a sudden increase of volume. The blood was then proved to be driven from one part of the body to another. He has also demonstrated that the application of cold water to certain definite parts of the surface exercise a positive influence upon definite vascular areas. Then cold applied to the feet affected the intracranial circulation; applied to the thigh, the pulmonary circulation; and to the back the mucous surfaces.

But not alone have these effects been demonstrated on the smaller vessels. The heart, too, has been proven to distinctly respond to temperature impressions upon the periphery, and that this result is brought about by reflex action is shown by Roehrig, who failed to obtain any action upon the heart when the vagi were severed. He demonstrated on the rabbit that moderate cutaneous irritations increase cardiac contraction, while they diminish them if they are intense and prolonged. These experiments, too, have been verified in man by Winternitz in Vienna and Delmas in Bordeaux, the only cities where hydrotherapy is practised in regular hospitals. Roehrig also had previously utilized his physiological experiments in the treatment of some heart diseases, in which cool baths (27° to 24° C.) reduced the frequency of the pulse, and he deduced from their application in other diseases also a confirmation of his physical experiments.

We therefore know positively that low temperatures, briefly applied, accelerate the heart's action, and that a prolongation of low temperatures diminishes it, as does also the reaction after a brief application. Also, that the application of high temperature to the skin produces a decrease of pulse rate, which is quickly followed by an increase. By the application of water of various temperatures to the surface for a lengthened period we obtain the direct effect of the cooled blood upon the heart. Experiments having demonstrated that heat applied directly accelerates, and cold diminishes, the heart's action, we can, by cooling the blood in fevers, produce an invigoration and slowing of the heart. And this is borne out by clinical experience, as we shall show later.

If, farther, as has been demonstrated again and again by the sphygmograph, the vascular tension may be modified at will by hydrotherapeutic procedures, we have another proof of our powerful influence over the heart's action. Indeed, so decided is this influence upon the entire circulation that hydrotherapy really reduces it to a hydraulic problem. As the blood stream moves in a definite, closed system, rapid changes in it can only, in the normal, uninjured state, be induced if the propulsive action of the heart is rapidly increased or decreased, or the capacity of the vascular area suffers fluctuation. All this has been accomplished by physiological experiment and verified by clinical experience. [The well-known tapping experiment of Goltz proves absolutely the powerful influence upon blood pressure and accumulation of blood in certain areas, which the removal of large masses of blood from other areas produces.]

When it is remembered how perfectly we can control these hydraulic changes by means of reflex as well as direct effects, through the agency of water of different temperatures, and how these changes may be varied upon an almost exact scale by careful attention to the degrees of temperature difference between the water and the recipient; to the degree of sensitiveness to impressions of the latter; to the extent of surface to which the application is made, etc., it is evident that we possess in hydrotherapeutic procedures a most *flexible* measure for influencing the vascular system.

The effect of thermic influences upon the temperature of the body is, perhaps, better understood than the effects referred to above. That the temperature of the body may be reduced has been so often demonstrated that all physicians are familiar with the fact; also that the human body is not affected by cold and heat like an inanimate body, but that it reacts against these thermic stimuli.

But it must be remembered that the vital processes by which the system endeavors to protect itself against thermic disturbing influences, are also definitely ascertained. The familiar example of shriveling of skin when extreme tolerable heat or cold are applied to the surface, is due to the vascular spasm and constringing effects of these thermic irritants. This vascular spasm protects the internal organs against too rapid cooling or heating. The secondary effect of cold or hot applications to the cutaneous surface are so well known that I need only remind you of them. Cold, if evanescent, is followed by reaction, which dilates the vessels forming heat, if evanescently applied, it is followed by dilatation, due to passive relaxation. When the superficial vessels contract in response to a more prolonged application of cold, there is a prolonged hyperæmia established in the nearest muscle tissues, which protects the body against the rapid invasion of the cooling blood; being thus supplied with more blood, more heat is produced. The prolonged application of external

heat, on the contrary, produces—as is familiarly known—an increased vascularization, and thus enhances its functions, with the result of increasing perspiration. A larger quantity of blood is retained in the relaxed vessels if the applications be prolonged, reducing the quantity in the muscles and other organs, and thus diminishing heat production.

By means of the calorimeter Winternitz has practically demonstrated that the going off of heat depends upon the cutaneous circulation. He has absolutely proved that the most active conditions of the skin functions may compensate three and a half times of the normal heat loss; or it may be increased three and a half times. As the great bulk of the heat is produced in the voluntary muscles which form about one-half of the entire body, it follows that the increased activity of the muscles, aroused by the external application of cold, is capable of producing an increase of heat.

Liebermeister discovered this in man in 1859, and it was confirmed by Hoppe's experiments on dogs, and later by Kœnig and Juergensen. But if the application of cold be prolonged or intense, the inner temperature sinks—as shown by Juergensen—rapidly. Liebermeister's experiments demonstrated that baths of sixty-eight to seventy five may be borne fifteen to twenty-five minutes ere the temperature begins to sink.

Delmas and Bottey have demonstrated the flexibility of hydrotherapeutic procedures on these principles. If the cold is applied briefly with a douche, according to Delmas, we have an intense sensation of cold, followed quickly by a general feeling of warmth; but during the reaction which ensues, the temperature continues to fall from 0.6 to 1.°, for two hours after the douche, especially if the patient exercises after it. Hence the simple sensation of cold or heat is not an index of the actual body temperature in health, any more than it is in the cold stage of an intermittent.

According to Bottey, if the douche is very cold (8° C., for instance) and lasts two or three seconds only, the fall of temperature is preceded by a brief period of elevation of 0.1° or 0.2°; but if the douche lasts ten seconds, there is no elevation at all, as Delmas has shown, but a fall, lasting several hours.

Upon the condition of the blood, also, the action of cold has been determined to be pronounced. Thernies has shown (in 1878) by very thorough investigations with Hayem's hæmatometer and calorimeter, that the number of blood globules was not only increased by the douche, but that their quality was improved. This mathematical demonstration, repeated by Winternitz, is verified, as I will have occasion to show by clinical experience.

The influence of thermic agents upon the nervous system has been so often demonstrated that I need only refer here to any special investigations. Physiological experiments have shown again and again that we may stimulate or depress it by reflex action.

47 E, 60TH STREET, NEW YORK.

The typhoid fever is subsiding in Philadelphia, there having been but seven deaths last week. The general death-rate of the city is very small at present.

The Polyclinic.

MEDICO-CHIRURGICAL HOSPITAL.

EPITHELIOMA OF NOSE.

HISTORY: Patient had always had a dark spot on the left side of the nose. It began to give him trouble about a year ago. Itching and slight pain occurred at times. The spot became red and inflamed, and, breaking down in the center, formed a small ulcer, which began to spread. This is a curable form of cancer, if treated in time. A concentrated solution of zinc chloride was applied last Wednesday, and allowed to remain for a few minutes, after which a dressing of ung. zinci oxidi carbolizat. was applied. This has afforded excellent results so far, and an operation is not considered advisable until this treatment fails. The chloride of zinc solution was ordered to be applied daily, with the same dressing as before. —*Pancoast.*

OPERATION FOR THE RADICAL CURE OF HYDROCELE.

Patient was a man, about sixty years of age, presenting a pyriform swelling on the left side of the scrotum, which is largest at the depending portion, translucent, and transmits an impulse on coughing. The patient had already been tapped several times, but the tumor returned so rapidly that it was decided to attempt a radical cure. Patient stood with his back against a table, and a broad-shouldered lancet was introduced into the hydrocele. A straw-colored liquid of high sp. gr. poured out. The tunica vaginalis was then scraped thoroughly, and the lancet withdrawn. This method is preferable to the injection of tincture of iodine.—*Pancoast.*

URETHROTOMY.

Patient was a man, about middle age, with a history of having passed a stone from the bladder, some years ago, which lodged near the meatus, and was removed through an incision, the meatus being too small to admit of its further passage. Urine was dark, strongly acid, without albumen or sugar, and with sp. gr. of 1.030. It contained acid phosphates, pus, epithelial cells, oxalate of lime, and uric acid. Patient was moderately well nourished, but melancholy, and suffering from considerable dyspeptic trouble. Acetate of potassium, gr. xv, three times a day, largely diluted, was ordered some time ago, and to-day the acidum nitro-hydrochloricum gtt. v, diluted with water, three times a day. Also quinine, iron, and strychnine were given as a tonic. A lotion of borax and glycerine was applied to the glans penis to soften any inflammatory deposit. The bowels were kept open with salines, and a full dose of quinine given to prevent shock.

The penis measured 11 cm. in circumference, and was therefore expected to have a caliber for the urethra of 35 mm. There were two strictures present—the first a tortuous one, near the meatus, and the second a linear one, about three inches from the meatus. The meatus was, a few days ago, enlarged with a bistoury and the tortuous stricture dilated.

To-day a solution of cocaine was injected into the urethra and a Gross' urethrotome passed, and the stricture divided. Then an Otis' divulsor passed into the urethra, set at 35, and the stricture forcibly dilated. If this plan fails, the operator suggested a trial of electrolysis; but he thought this would be all that would be necessary, the dilation being kept up by passing the sound.—*Goodman.*

A letter-carrier complained of vertigo, and headache, which were temporarily relieved by cardiac depressants. Examination showed that he had mixed astigmatism of one eye, and irregular astigmatism in the other, probably due to irregular curvature of the lens.—*Fisher.*

New growths are the results of irritation, which is is always due to a dead, chemical agent, or to a living, vital one, the latter acting mechanically, or through the medium of noxæ generated by it. This fact has put a new face upon pathology.—*Laplace.*

Not a single case has yet been recorded in which the tubercle bacillus, having been discovered in the sputa, has totally and finally disappeared during the patient's life.—*Laplace.*

Wounds of the knee joint once considered essentially fatal, are now, under antiseptic measures, no more dangerous than cuts of the finger.—*Laplace.*

Out of several hundred cases in which the bacillus tuberculosis was demonstrated in the sputa less than two years ago, not one is now alive.—*Laplace.*

The disease formerly known as the white swelling, simple, or with fungosities, we now denominate local tuberculosis of the knee joint.—*Laplace.*

The experience of half a century has demonstrated that there is no better local antiphlogistic than lead-water and laudanum.—*Garretson.*

FRACTURED RIBS.

In the treatment of fracture of the ribs, Dr. Morton, of the Pennsylvania Hospital, has discarded adhesive plaster on account of the difficulty of changing or removing it, and because it is uncomfortable to the patient, especially in hot weather. He uses an extemporaneous corset made of canvas, fastened with lace strings. He takes the circumference of the chest four or five inches above and below the fracture, so as to make the apparatus about ten inches wide. It is made a little long so that it may be drawn tighter after it is applied. There are two rows of hooks, and lacing-strings are put through them to draw them up. The instant that it is put on and properly adjusted the patient is free from pain.

PHILADELPHIA HOSPITAL.

AORTIC ANEURISM.

I HAVE here two cases of unusual interest, the first of which presents a history as follows: White woman, aged thirty-one, and a domestic, has used liquor for fifteen years; is married and has no children. In 1887 she began to feel shortness of breath upon exertion, and had pain in her left elbow and sides. She was apparently cured. She returned this year with a throbbing pain in her chest, palpitation of the heart, and a full feeling in the head, with dizziness. I find a pulsating tumor at the second interspace, one inch from the left border of the sternum. The patient has an aneurism of the aorta, but it is rarely that they are found to the left of the sternum, as in this case. There is hypertrophy and dilation of the left auricle, with the sound of a double bruit. With inspiration there is evidence of an œdematous condition of the lungs and moist rales. We must take into account the cause of this trouble. Syphilis may produce it, but this is negative here. Use of alcohol is the next most common cause, and is a slow process. It is probably the cause in this case. Rest is to be enjoined that the heart may not beat so much, and thus relieve the force of the circulation. The starvation treatment consists in giving as much food as will merely sustain life in the hope of thickening the blood, and causing coagulation in the aneurismal sac. Electrolysis cured one small aneurism of which I know. This woman's treatment has been the bromide of potassium; compound infusion of gentian, bismuth sub. nit., and paregoric for diarrhœa, as well as potassium iodide ʒjss daily.

The next case is a white woman, aged forty-four, a domestic. She menstruated at fourteen. Two years ago she took a pain in the left arm above the elbow, which was worse at night. The arm felt as though encircled with a vice, and the pain extended across the chest and angle of the scapula. The pain is sharp and stabbing in character. Pulsation is felt in the chest, with paroxysmal dyspnœa and pain. I find an aneurism of the aorta at the left of the sternum, which is larger and more tender than in the preceding case. She has had a cough for two months, which is due to the pressure of the aneurism on a bronchial tube. She has received the same treatment as the other case; but takes of the potassium iodide gr. xx, as well as nitrite of amyl for the dyspnœa.—*Curtin.*

SOME DISEASES RECENTLY DESCRIBED.—*Disease of Morvan.*—This is a nervous disease that begins with numerous felons, producing deformities of the fingers. There are, at the time, trophic disturbances of the skin, muscles, bones and anomalies of sensibility. Gombault, at an autopsy, found diffused sclerosis of the spinal cord.

Syringomyelia.—This disease begins a progressive atrophy of muscles of the hands, gradually progressing to those of the arms and chest, sparing the face and lower extremities. There is abolitien of thermic sensibility of the skin and diminution of dolorific, the tactile sense remaining intact. It depends upon a neoplasm of the anterior portion of the spinal cord, especially of the cervical region.

Acromegalia.—This disease develops at any age. The principal symptom is a hypertrophy of the extremities, sometimes the fingers only being affected. This disease proceeds symmetrically. According to some authors, it is dependent upon an alteration of the thyroid gland and a persistence of the thymus.

THE ABUSE OF CHARITY.

THIS time-worn subject is being vigorously handled just at present by our British brethren, and for the last few months it has furnished many columns of amusing and instructive reading-matter in the *British Medical Journal.* A series of resolutions, coupled with a scheme for the establishment of a Public Medical Service, was introduced by Dr. Rentoul, of Liverpool, before the Leeds meeting of the British Medical Association. The Council took the matter in hand, and is now pushing it forward in a manner that promises some sort of reformation in regard to the abuse of the medical charities. The various branches of the Association have been requested to discuss the matter, and both collectively and individually to express their opinions directly to the Council or through the columns of the Journal.

There is general agreement that a reform is absolutely necessary. The three principal methods of affording cheap medical attendance to the poor now in vogue are all condemned for various reasons. The out-patient departments of the great hospitals are of no real advantage either to the profession or to the laity. The former are degraded into using it as a means of self-advertisement, and the latter are educated by it into some of the worst habits of pauperism. The way that patients come and go in a dispensary service prevents all chance of that close observation and careful treatment which might render it of real service, either to themselves or for the further advancement of science. As for their educational advantages to the student, dispensaries are not as beneficial as the well-filled wards of a good hospital. The disadvantages of this system, both in depreciating the returns to the general practitioner and in favoring pauperism, are quite self evident. The provident and club systems, whereby any person, who so desires, can pay a small annual contribution and then receive at any time the treatment of the attending doctor, are accompanied with still greater defects. For as none of these latter charities are entirely self-supporting, the treating of patients who may be members of them, and at the same time fully able to pay for private attendance, is a gross injustice to the people who benevolently subscribe for their maintenance, thinking that they are thereby helping the poor and needy. There is nothing so mean as the robbing of the poor; and if there are people contemptible enough to crowd those who are in actual want out of the benefits of the medical charity, and of the needed attention of the attending physician, they should be prevented from so doing in some way by the medical profession itself.

It is for this reason that Dr. Rentoul has elaborated his scheme, to be known as the Public Medical Service. There are many details connected with it which render it in its present form more or less impracticable. Its principal object is to determine by a "wage limit" who should and who should not be eligible for out patient medical aid, and then to charge in accordance with a schedule of prices arranged in harmony with this "wage limit." So determined is the Council of the British Medical Association to attempt to right the evil, that they have published on a separate page of the last Journal the plan and resolutions of Dr. Rentoul, leaving a blank space for each member to fill in with his own comments, and then return the same so that they may act for the advantage of all.

The first rule suggests that when a man and wife make 25*s.* per week and over, or a single person 20*s.* per week and over, they shall be ineligible for out-patient treatment at the medical charities—except in cases of accident—and that those earning a similar rate of wages shall be ineligible for "home visits," that is visits paid by the staff of the medical charities, to sick persons at the patient's home. It is further suggested, that in order that those who shall be excluded from the out-patient department of the medical charities may have the means of obtaining immediate and efficient medical, surgical and dental treatment and also medicines, a Public Medical Service be formed, embracing those wage earners who are making under 45*s.* per week, per family, and single persons under 30*s.* per week. It is recommended that in connection with this service, a periodic payment be made by the members during health; that a sliding scale of payments be made to their medical practitioners; that the minimum medical fee paid by such sick clubs be 6*s.* per annum per member; that the person proposed for membership pay a fee of 3*s.* 6*d.* for the medical examinations (whether admitted to membership or not) to the practitioner who so examines; that the sum of 1*s.* be paid for each certificate to the practitioner by the person who obtains it, and that the sum of 8*d.* be paid for each prescription dispensed. A schedule of charges for the general run of surgical operations and obstetrical cases has also been elaborated. Of course such a scheme meets

with considerable opposition, chiefly from those personally interested in the existing systems. The general practitioner and suburban doctors generally favor it, while the consultants of the large cities are significantly reticent in regard to the expression of any opinion. The House of Lords has been appealed to praying for an enquiry into the management of the Metropolitan Medical Charities; and if they take action reform of some sort may possibly follow.

We shall watch with interest the outcome of all this, but without wishing to be pessimistic, we are more than doubtful of its ultimate success, because of the general apathy of the profession. It is singular how indifferent medical men are, when called upon to act collectively for the protection of their own interests. They talk about charity and the blessed art of healing, and yet they forget that the greatest charity begins at home. It is proverbial how unbusiness-like doctors are, yet, at the same time, the well-known fact is anything but complimentary that the average doctor's family rarely enjoys the luxuries of life, and not unfrequently wants for the actual necessities. There is a good deal of vapid sentimentalism talked about the medical art. Why should the practice of medicine be more of a charity than the keeping of a grocery store? Both cater to human wants and the feeding of a hungry man is as noble a charity as the administration to a sick man of a dose of medicine. Knowledge certainly has a marketable value, and if we remove the incentive which springs from the reward that belongs to knowledge and skill, the inevitable result will be, as can here and there be discerned even to-day, to keep out of the professions the brightest intellects. Unlimited means will never make a man as shrewd an observer and as close a student as if he were forced to cultivate his intellect in the hope of acquiring the rewards of superior knowledge. Any biography will afford instances of the truth of this.

But charity is not always the score upon which doctors excuse themselves for neglecting to demand the just remuneration for their services. We have known of instances where medical men enticed patients from their confreres by offering to treat them at their offices gratuitously; and it is well-known how the dispensaries are used to "feed" the office practice of specialists. Hospitals, colleges and dispensaries are considered by many as good advertisements. Some one has jocosely remarked that in college-crowded Chicago "professors" are so numerous that a common doctor is quite a rarity, which reminded the same individual of an incident in Boston a few years ago, when a professor requested his friend not to address him as such upon the street, lest he be mistaken for a boot-black. At one time to be connected with a hospital meant particular ability in some department of medicine. but things have changed with the rapid growth of these institutions in our midst. The temptation to start a dispensary or open a private sanitarium has become simply irresistible. In all professions the only legitimate advertisement is one's own ability, and rarely does an industrious man fail when he has that.

The whole question of medical reform, so far as the private practitioner is concerned, seems to us to depend solely upon the principle of supply and demand. A man who does not make a living and continually cries out against the charities, may be pretty sure that he himself is not quite up to the mark as to skill and tact. The dispensaries are abused, without doubt, but it is more than utopian to hope to suppress them or limit the attendance of the laity upon them. How is one to learn of a man's income, and so set the wage-limit? How is the matter to be equalized, even after one does learn it, since a wage earner's means is a relative factor according as he has a large family, is a bachelor or possesses a permanent or unsteady situation? It is rare that those who are at all able to pay care to be regarded as objects of charity, hence by admitting all applicants as charity patients to a hospital, we would rarely be obliged to turn away any because they were able to pay for treatment at home. Though we recognize the evils of our overgrown charities, and would like to see some reform introduced, by reason of which their benefits would fall to those who really deserve them, we cannot see any better plan for the present than that of simple competition. They cannot be regulated any more than ordinary trade, and for the state to manage them, would involve the passing of sumptuary laws.

A WARNING.

SURROUNDED as we are by all sorts of micro-organisms, we must be in a continual state of watchfulness to avoid every possible source of infection. Though we may be familiar with the causes of the infectious diseases, and up to a certain point know how to combat these causes, we are often so negligent as to fail to recognize them until they have exercised their baneful influence. In these days of antisepsis, one would almost imagine that there was not a ghost of a chance left for any pathological germs to enter the human system. Such is not the case, however. For it is not enough that antisepsis should be limited to the operating room only. When we remember what splendid opportunities are afforded for the transmission of these infectious diseases by the midwives, dentists, hair-dressers, and barbers who are ignorant of the nature of these diseases, and indifferent as to general cleanliness, we may well be surprised that so many of their customers escape contamination. It would be fortunate if all such occupations could be closely watched, and proper regulations enforced for the protection of the people; if antiseptics could be insisted upon or at least absolute cleanliness maintained. If in every case of infectious disease where trouble was positively found to have originated in this way, the midwife, dentist or barber could be made liable to fine and punishment, the

danger would undoubtedly be greatly diminished. The mere keeping of one's own shaving cup and toilet articles in these shops is not sufficient protection, for the hands and the finger nails are liable to carry the virus or germs from one individual to another. It is not a comforting thought that one's predecessor in the arm-chair may have been the victim of scabies, or that the barber's hands now rubbing our own head may have been scratching up nests of pediculi in the head of the man who has just gone out. It is not very solacing to imagine that one's dentist may be using an instrument which has just been employed in the mouth of a syphilitic. But since these occupations are indispensable to civilization and must needs be patronized, the only safe remedy would, of course, be strict supervision in regard to cleanliness, and so far as possible rigid maintenance of the best methods of antisepsis.

In 1864 and 1865 there was a kind of epidemic of syphilis in Paris, most of the cases of which were reported to the Société des Hopitaux, wherein the cause was clearly traced to the operations performed upon the nose and ears by a specialist, who did not trouble himself to thoroughly wash his instruments. Such negligence would of course not be tolerated at the present day; furthermore we should like to see such gross carelessness made a criminal offense.

It seems almost incredible, and yet it is a positive fact, that there are operators even to-day who disregard all the teachings of pathology and bacteriology, and either carelessly or wantonly use instruments and dressings that are not thoroughly antiseptisized. Lancereaux has lately reported to the French Academy of Medicine two well-marked cases of constitutional syphilis, in which the infection could be directly traced to the instruments used by a surgeon in his earlier operations. In the first case, a man of robust physique and fifty-three years of age, whose previous history had been above reproach, the catheterization of the Eustachian tube was the beginning of the trouble. In the second, a woman thirty-six years of age, it was unmistakably traced to the operations of a dentist upon the upper jaw. In both instances, not only did the initial lesions pass through the usual stage, but later on all the usual secondary symptoms made their appearance in the most pronounced manner. The careful investigation of these two cases placed the diagnosis and origin of the disease beyond a doubt.

The lesson to be drawn is obvious enough, but it cannot be too vigorously enforced. Whether antisepsis be admitted as a necessity or not by the surgeon, absolute cleanliness should invariably be. In fact a surgeon known to be careless and indifferent in his habits should no more be allowed to perform an operation than an inexperienced student should be allowed to administer powerful drugs. No instrument should be employed without being thoroughly cleaned and subjected to heat, or better still the carbolic acid solution. Whether the sublimate solution or any other antiseptic be employed in the washings and dressings, it should always be insisted upon.

If we fail to secure complete immunity from contamination in some of the humbler occupations of life, let us not have it said that medicine is in any way the cause of diseases which it is striving to cure.

Annotations.

A NEW REMEDY FOR DYSENTERY.

THE *Boletin de Medicina*, of Santiago de Chili, gives a notice of a new plant, which is said to be a wonderful remedy for dysentery and diarrhœa. The sketch was presented to the Chilian Medical Congress by Senores Daniel Carvallo and Emilio Eisene. The plant is named "*el bailahuen*," and its botanical title is "*haplopappus baila huen.*" It is a native of the Cordilleras of the Andes, between 20 and 30 degrees of south latitude.

The shoots of the bailahuen are soft, glutinous and smooth, and the virtue of the plant lies in all parts. It is prepared as a tincture, a fluid extract and as an alkaloid. Its therapeutic effects have been shown in a number of cases of dysentery, indigestion, diarrhœa, metritis and sexual impotence. It appears that this Chilian plant possesses valuable properties in dysentery, operating somewhat after the manner of ipecac without its nauseating qualities and with a more durable result. After its use there is no need for a purgative to restore the bowel action. In other diseases referred to beside dysentery and diarrhœa, experiments have shown it to be valueless.

CIVILIZATION *vs.* BARBARISM.

LANCEREAUX (*Revue de Therapeutique*) has opened a campaign against the outlying allies of the medical profession, the barbers, to compel them to keep their instruments in strictly absolute asepsis. Truly, it is not pleasant to reflect that the cushioned chair in which you rest has just been occupied by a sufferer from pediculi, the arms on which your hands rest just sustained those of a boy with scabies, the razor has shaved a hundred men, cutting through pimples and scraping off epidermis with possibilities of tinea, syphilis, tuberculosis, pemphigus, sycosis, etc., etc.; while the soap-cup and brush! Can those things *ever* be really clean?

AN EPIDEMIC OF ROSEOLA.

IT appears from an article in the *Revista Medica*, Chili, signed by Dr. Ugarte, that they have been having in the city of Santiago a very extended epidemic of roseola. In its different forms, benign or more intense, its infectious or infecto-contagious character was very evident.

The eruption began usually upon the forehead, spreading thence with great rapidity. The duration of the disease was from twenty-four hours to four or five days, and it presented two forms, one cold, the other hot. There seemed to be also an infection of the blood by toxic substances from the liver, and these entered the blood in sufficient quantities to provoke fever.

The treatment usually adopted was administration of large doses of calomel followed by a neutral salt. At the same time, the intestines were disinfected, and the functions of the skin carefully attended to. The mortality was exceedingly slight.

CIUDAD BOLIVAR MEDICO.

WE have received a number of a little medical magazine, bearing the above title, coming from a city six hundred miles up the great Orinoco river. It might be readily supposed that at this distance from the centers of civilization, a medical magazine would have hard work to exist; but those who think in this way, are unacquainted with the energy and scientific training of our Venezuelan brethren.

In this little town, so far inland, the medical fraternity is at once studious and well-posted in what is going on in the great world.

At the head of the profession is our old friend Dr. Doroteo de Armas, who is also rector of the University.

Among the notices in this journal we find that beriberi is making about the same ravages as in former years, and that it is found as difficult to cure as before; also a notice of a rare plant, the peculiarity of which is that its seeds are able to move and even to spring from the seed capsules of their own accord.

We welcome the new journal to our table, and hope to hear frequently from its talented contributors.

CATRAMINA.

CASATI states that *catramina*, isolated by Bertelli from the tar of *abies canadensis*, is endowed with a specific action against the bacillus tuberculosis. In gelatine cultures, catramina arrests the development of the bacillus and kills it. For this it requires three drops, to five grammes of culture fluid. The drug has been given to rabbits in considerable doses, for long periods, without injury to the health.—*Med. Zeit.*

[This would require a dose of six pounds to render aseptic the body of a man weighing one hundred and fifty pounds.]

THE report of the New York Analyst of Drugs shows that the chances for getting drugs of good quality on prescription is 43.8 per cent.; fair, 17.4; inferior, 26.; not as called for, 11.6; excessive strength, 1.2.

A PALATABLE LAXATIVE.—Make a strong concentrated infusion of senna leaves; strain this through a muslin cloth, and boil in the strained liquid as many *prunes* of good quality as can be well boiled in the quantity of infusion. Stew the prunes in the liquor thoroughly, in the same manner as if for the table, properly seasoning. When well cooked put in a glass jar, screw the top down tightly and set away in a cool place. Two or three or four of these prunes eaten during the day will overcome some of the severest cases of constipation. There is no suggestion whatever of the senna in the taste of the prunes, and the effect is most desirable. If taken at bed time, when a laxative is desired, the bowels will move nicely in the morning. They can be taken on the most sensitive stomach, and when other laxatives would produce undesirable results.—*Chi. Med. Times.*

Letters to the Editor.

CORRECTION.

YOUR reporter, in crediting me with "Fifty-three successive ovariotomies without a death," in the TIMES AND REGISTER for the 16th ult., misunderstood my statement, and I beg leave to correct his error.

What I said, in reply to a question by one of the spectators as to my results with laparotomy, was, "If this case recovers, as I see no reason to doubt at present (and as she did, without a drawback), it will be my fifty-third successive *ovariotomy*, with but one death, and that was an intraligamentous ovarian cyst, the very worst variety of such tumors for removal. That patient died of septic peritonitis."

I also added that the ovariotomies included many bad and difficult cases, such as ovarian abscesses, adherent dermoid and multilocular cysts, with purulent contents, and universally adherent pus-tubes, not more than two or three being uncomplicated cysts.

Since then I have done three more ovariotomies—one a very bad case of ovarian and tubal abscess, with universal adhesions, all of which have recovered, making thus *fifty-six successive cases of recovery from removal of diseased ovaries*, either tumors or adherent and inflamed, with but one death—the thirty-third in the series.

During this time I had two fatal hysterectomies for fibroids, one death (from heart-failure) after ventrofixation for prolapsus, and one from exhaustion after abdominal section for purulent peritonitis. But these operations should not, I think, be classed with ovariotomies proper.

PAUL F. MUNDÉ.

NEW YORK CITY.

MATERNAL IMPRESSIONS.

HAVING noticed considerable controversy *pro* and *con* in reference to maternal impressions, recently, in medical journals, we submit the following interesting item without comment: On Friday evening last there was born to the wife of Geo. W. Curtis, of Weston, a girl baby, who was eyeless. The unfortunate little being is not only sightless, but is disfigured by having not even the semblance of eyeballs, the orifice where the eyes should have been being but slightly marked. The child is lively and healthy, but the beauties of this world, or that portion of them that are conveyed to the mind through the retina of the eye, must forever remain a sealed book to her.

"Its parents are at a loss to account for its lamentable peculiarity, but it may be due to the following singular circumstance: Six months before the birth of the little one the mother became totally blind at sundown, but in the morning her sight was restored. Thinking the trouble was due to the affection known as 'wild hairs,' she removed her eyelashes, one at a time, to rid herself of the evil."—*Oregon Journal.*

Opponents of the theory of maternal impressions will please make a note of the above facts and explain upon what other hypothesis this wonderful freak of nature could have occurred.

HAINES, BAKER CO., OREGON.

Society Notes.

THE SOUTHERN SURGICAL AND GYNÆCOLOGICAL ASSOCIATION.

Second Annual Meeting held in Nashville, Tennessee, November 12, 13, and 14, 1889.

NOVEMBER 12.—FIRST DAY.—MORNING SESSION.

[Continued from page 740]

SECOND DAY—MORNING SESSION.

DR. GEO. J. ENGELMANN, of St. Louis, read a paper entitled

MENSTRUATION AND PREGNANCY AFTER REMOVAL OF BOTH OVARIES.

The following are the conclusions drawn from the history and microscopical examination of Dr. Engelmann's cases, which are corroborated by numerous cases of oöphorectomy and double ovariotomy now observed, whose histories have been recorded for a sufficient length of time after the operation:

1. That the continuance of menstruation after the removal of both ovaries is due to remnants of ovarian stroma left *in situ*.

2. That portions of the ovarian tissue, however small, which remain after the removal of the greater portion of the organ, whether or not the Fallopian tube be preserved, may retain their activity and continue the functions of the entire organ.

3. Even elongated pedicles may contain ovarian stroma in which the functional activity of the organ may be continued.

4. That remnants of ovarian stroma do not necessarily preserve their vitality and functional activity.

The deductions of practical value to the operator are even of greater importance, and they are these:

(*a*) For the successful performance of oöphorectomy, it is requisite that every particle of ovarian stroma shall be removed if the desired result is to be expected with certainty.

(*b*) If shrinkage of fibers, the limitation of hemorrhage or cessation of annoying symptoms is to be accomplished with the greatest certainty, both ovaries must be completely removed, and not even a particle of ovarian tissue left *in situ*.

(*c*) In the performance of double oöphorectomy in women not yet beyond the climacteric, and not suffering from utero-ovarian reflexes, such healthy ovarian tissue as may exist should be spared, in order that function activity may not be impaired.

DR. W. D. HAGGARD, of Louisville, said it is very rare for a woman to menstruate regularly after removal of both ovaries and both tubes. He believed that the hemorrhagic discharges from the uterus after oöphorectomy depended upon some other cause than that of menstruation. It may depend upon some trouble connected with the endometrium, as suggested by Dr. Engelmann, a polypoid growth, or a congested condition of the bloodvessels which supply the endometrium. In January last he removed both ovaries and both tubes in a woman, and it is barely possible bits of ovarian stroma were left behind, as three months later the patient continued to have hemorrhagic discharges which greatly annoyed her.

DR. A. W. JOHNSTONE, of Danville, Ky., held that the ovary has no more to do with menstruation than the clitoris has. To prove this he had left ovarian tissue behind, yet menstruation had ceased. Dr. Johnstone gave at length his reason for this theory.

DR. VIRGIL O. HARDON, of Atlanta, Ga., had operated on a patient about eighteen months since for a bleeding fibroid tumor, removing both ovaries, and in removing the second ovary he feared he had not removed all the ovarian tissue, as the precarious condition of the patient would not permit a continuance of the operation. The patient recovered from the operation, and has menstruated with unvarying regularity from that time to the present.

DR. RICHARD DOUGLASS, of Nashville, said that Battey's operation of itself does not control menstruation, whereas in Prof. Tait's operation, which consisted in the removal of both ovaries and both tubes, the gynæcologist embraces in his ligature the nerve which controls menstruation.

DR. A. V. L. BROCKAW, of St. Louis, warmly took exception to the remarks of Dr. Johnstone, who was inclined to give Tait the credit of first performing oöphorectomy. He said he admired Tait's skill as an operator, but as a man he did not, for with characteristic modesty he (Tait) adds his name to operations that do not rightfully belong to him—as, for instance, the flap splitting operation.

Dr. Brockaw's remarks were warmly applauded.

DR. W. H. WATHEN, of Louisville, said gynæcologists were more familiar with the laws that govern menstruation in many respects than they formerly were, but that we still require more scientific investigation, personal observation, and experience to convince us that any one cause controls menstruation.

DR. A. W. JOHNSTONE arose to defend an absent friend. The statement made by Dr. Brockaw that Tait was the originator of the flap splitting operation is not true. A full description of the method could be found in a recent issue of Mundé's journal. It is true, however, that Tait had used it without knowing it had been described some twenty years ago by a Dublin surgeon; but he has given him due credit for the operation.

The paper was further discussed by DRS. G. FRANK LYDSTON, of Chicago; JOHNSTONE; and discussion closed by DR. ENGELMANN.

Dr. Davis's paper, which will appear in this journal shortly, with illustrations, was followed by one entitled

INTESTINAL ANASTOMOTIC OPERATIONS WITH SEGMENTED RUBBER RINGS, WITH SOME PRACTICAL SUGGESTIONS AS TO THEIR USE IN OTHER SURGICAL PROCEDURES,

by A. V. L. BROCKAW, of St. Louis, Mo.

For many months the author has been experimenting with segmented rubber rings in all the anastomotic operations, and such operations as gastrostomy, cholecystotomy, duodeno-cholecystotomy, jejuno-cholecystotomy, and circular enterorrhaphy. The rings used by him are rapidly made—during an operation if necessary. All that is required is some rubber tubing or a soft ordinary rubber catheter, and some catgut. He prefers tubing one-sixteenth to one-eighth of an inch in diameter. A section of this,

of sufficient length to make a ring of the desired aperture, is cut into four to eight segments. Passing heavy strands of catgut through the lumen of these pieces, the ends are tied tightly enough to bring the ends of all segments together, forming an oval ring. To the catgut strands are tied from four to six silk apposition threads, twelve to fourteen inches long, and the attachment of needles to these threads renders the ring ready for use. Another method is to pass a heavy double strand of catgut continuously through the segments several times; approximate the ends of the segments, and push the ends of the catgut into the tubing. This ring will have a better surgical finish, and after the apposition threads are tied between the segments, the ring will maintain its perfect form until the catgut is absorbed. The rings were passed as early as the fifth day in one of his experiments. In forming an anastomosis, after ordinary No. 6 darning needles are attached to the apposition threads, compress the ring and pass it through the opening made in the lumen of the bowel, then pass the threads through the intestinal wall from within outward. Ascertaining that the ring rests well in place, proceed to the second in the same manner; appose, and after scarification of the marginal serous surfaces, as suggested by Senn, tie the apposition threads. When possible, it is well to utilize omental grafts, which add to the security. With two such rings circular enterorrhaphy may be performed, the rings corresponding in size to the lumen of the bowel, care being taken that they are not so large as to press too much upon the delicate mucosa or to overstretch the bowel, as a local gangrene might then follow. Introducing a ring at each end of the gut at the point of section, the threads are passed through the wall less than one-third of an inch from the divided margins. The distal end of the gut is invaginated and the proximal gut pushed into the distal, bringing the serous surfaces in contact. The threads are then tied, and a few Lembert sutures added, the entire operation requiring less than ten minutes. In one-half of his experiments with this operation the result was excellent. Of the 14 dogs operated on by this method, in 7 the results were all that could be desired; marked stenosis was found in several cases, and in all a ridge at the seat of the operation.

In a recent paper the essayist mentioned a new procedure of closing large wounds of the intestines, especially gunshot, where, by ordinary suturing, stenosis would result. This method applies to wounds of the surface of the intestine; those of the mesenteric portion usually require resection. By this simple method wounds the size of a half dollar may be closed in less than five minutes. The wound being trimmed and enlarged with scissors, a ring two-and-a-half inches in diameter, made of eight segments of tubing, with six apposition threads, two on each side, so arranged that when the apposition threads are tied the ring is held bent evenly on itself. Such a ring is introduced into the bowel, the end apposition threads passed, then the lateral, using a single catgut suture in drawing the wound margins together at the point of flexure in order to prevent eversion. A few Lembert sutures complete the operation. If two wounds are close together in the same loop, a lateral anastomosis might be formed, if possible. With more than two wounds close together, excision and lateral anastomosis will require less time than circular enterorrhaphy or the sewing up of several wounds. Other conditions, where the single ring may be used, are perforating ulcers, fistulas, etc. The great advantage of the segmented rubber rings over other devices used, is the simplicity of their construction and the rapidity with which any number may be made. The large aperture of segmented rings makes it possible to perform ileo-colostomy by the following method, which the author believes is original: The ileum being divided a short distance from the cæcum, the divided end of the distal bowel is invaginated into itself and secured by a continuous suture through the serous and muscular coats. Above the proximal end a clamp is placed, and a ring adjusted to the lumen; a slit is then made in the convex surface of the ascending colon, and a ring introduced. The bleeding checked, the proximal end of the divided ileum is inserted into this slit, the threads tied, and Lembert sutures added. This operation may be quickly performed, and is indicated in such cases as irreducible intususception of the ileum into the cæcum, and malignant diseases of the colon.

Appended is a series of operations, with the results:

Gastrostomy—2 experiments, 2 recoveries.

Gastro-jejunostomy—3 cases, 2 recoveries, 1 death from peritonitis. (Dog tore one suture eight days after operation.)

Jejuno-ileostomy—1 case, result perfect.

Ileo-ileostomy—2 cases, 1 death due to perforative peritonitis.

Ileo-colostomy—2 cases, 2 perfect results.

Colo-colostomy—3 cases, 1 death.

Ileo-rectostomy—2 cases, perfect results.

Circular enterorrhaphy—14 cases, 2 deaths.

Duodeno-cholecystotomy—3 cases, 2 deaths from peritonitis. (This operation is difficult to perform on a dog, for anatomical reasons.)

Partial duodenectomy—2 cases, 1 perfect result.

Partial jejunectomy—2 cases, 2 perfect results.

Partial ileo-ectomy—4 cases, 1 death.

Partial colectomy—2 cases, 2 perfect results.

Summary—Intestinal anastomotic operations, 14 cases, 3 deaths. Circular enterorrhaphy, 14 cases, 2 deaths.

The single ring, formed of eight segments of tubing, was used in closing wounds varying in size from a quarter to half a dollar, in 9 cases, with 1 death. The clamp devised by him, and used in the operations, is made of No. 12 copper wire, covered with unperforated rubber tubing of small size.

Discussion postponed till afternoon.

Afternoon Session.

The papers of Drs. Davis and Brockaw were discussed by Drs. W. O. Roberts, Virgil O. Hardon, B. E. Hadra, A. M. Owen, Hunter McGuire, W. W. Potter, R. S. Cunningham, G. Frank Lydston, Richard Douglas, Geo. J. Engelmann, W. E. B. Davis, and discussion closed by the essayists.

(To be continued.)

Camden Letter.

SINCE my last letter to the TIMES AND REGISTER, detailing the doings of the medical men of Camden, we have passed through the pleasurable excitement resulting from the meeting of two of our societies.

On Tuesday, November 12, the Forty-third Semi-annual Meeting of the Camden County Medical Society was held in this city, with the President, Dr. William A. Davis, in the chair, and the Secretary, Dr. E. L. B. Godfrey, present. There was a large attendance of physicians from all parts of the county, and also Prof. John V. Shoemaker, of your city.

The proceedings were of a very interesting and animated character, the attention of members being sustained nearly four hours by the reading and discussion of the important papers presented. Dr. H. A. M. Smith, of Gloucester City, Chairman of the Section on Practice of Medicine, introduced Dr. W. S. Jones, of Camden, who read a paper entitled, Reflex Diseases of the Upper Air Passages.

Dr. Dowling Benjamin, Chairman of the Section on Surgery, read a short paper on Trephining the Spinal Cord for Fractures, in the course of which he briefly described the operation performed at the Cooper Hospital, recently, for the relief of a man who had, by a fall, fractured the fourth cervical vertebra. This subject is of such great interest and importance that we hope the doctor will elaborate his paper and publish it. Dr. Benjamin also described the technique of an operation for the removal of an ovarian tumor with very extensive adhesions; and before resuming his seat he exhibited to the Society an ingenious apparatus, which he had devised, for the rapid rolling of the plaster of Paris bandage. Dr. O. B. Gross gave the history of a case in which a large bean was found in the left bronchus; and described a singular accident which resulted in rapid œdema of the glottis and death, before help could be obtained.

Dr. Daniel Strock, Chairman of the Section on Hygiene, read a lengthy paper entitled, The Camden City Water Supply, which was listened to with close attention, and thoroughly discussed. Dr. John R. Stevenson read a paper upon the Hygiene of Haddonfield.

In the Section on Obstetrics, of which Dr. Edwin Tomlinson, of Gloucester City, is Chairman, the only paper offered was by Dr. E. L. B. Godfrey, entitled, Puerperal Convulsions. This was an excellent presentation of the subject, and stimulated an animated discussion.

Dr. Joseph H. Wills, Chairman of the Section on Pathology, described the bacillus of typhoid fever, and exhibited a specimen with his microscope.

After the meeting the Society repaired to the dining-room and partook of an elaborate banquet, during which the following toasts were offered: Higher Medical Education, which was eloquently replied to by Prof. John V. Shoemaker; The Camden County Medical Society, responded to by Dr. H. Genet Taylor, ex-President of the Medical Society of New Jersey; The Camden Training School for Nurses, responded to by Dr. Daniel Strock; The Camden City Medical Society, to which its President, Dr. E. L. B. Godfrey, happily replied; Medical Co-Education, to which Dr. O. B. Gross fittingly answered.

On Thursday evening, the 14th instant, the Camden City Medical Society held its regular monthly meeting, with Dr. E. L. B. Godfrey, the President, in the chair. The subject of discussion for the evening was, the Treatment of Tuberculosis, which was participated in by Drs. H. Genet Taylor, D. Benjamin, W. H. Iszard, G. T. Robinson, A. M. Mecray, R. Casperson, E. P. Townsend, W. H. Ireland, and others. The discussion was impromptu, as the essayist appointed for the evening was not present, and it developed the fact that the Society was well informed upon all that pertains to the varied and latest treatment of this disease.

The Camden Training School for Nurses, the exercises connected with the opening of which I detailed in my last letter, is already upon a firm business foundation. The number of pupils enrolled has exceeded the most sanguine expectations of its promoters; and the best element of Camden's people attest their approval of, and sympathy with, the movement by crowding the lecture-room upon every occasion of lectures.

The Fifteenth Annual Meeting of the New Jersey Sanitary Association was held in the State House, at Trenton, on Friday and Saturday, November 22 and 23. Three of Camden's physicians enacted a more or less important part in the proceedings, which were of an unusually interesting character. The President, Dr. Dowling Benjamin, of this city, occupied the chair. At the Friday evening session he read his annual address, entitled, The Thermometry of Hygiene. This was an able and timely paper, and was received with great applause by the large audience of distinguished gentlemen present. Dr. E. L. B. Godfrey, of this city, in an interesting speech, opened the discussion on the subject of The Need of Medical Officers for School Districts; and Dr. Daniel Strock, also of Camden, discussed the Climatic Treatment of Gastro-intestinal Diseases in Children.

CAMDEN, NOV. 20, 1889.

Book Reviews.

KRITIK DER VACCINATIONS STATISTIK, UND NEUE BEITRAGE ZUR FRAGE DES IMPFSCHUTZES. Von JOSEF KÖRÖSI. Berlin: Puttkammer u. Mühlbrecht, 1890.

The world owes much to the learned and industrious Director of the Budapesth Bureau of Statistics for the manner in which he has detected and demonstrated the astounding way in which the anti-vaccinationists had manipulated the official statistics of Austria in order to make them support their theories. It is sufficient to say that henceforth it will require more proof than the personal assertions of this party to win credence.

AN EXPERIMENTAL STUDY IN THE DOMAIN OF HYPNOTISM. By DR. R. VON KRAFFT-EBING, Professor of Psychiatria and Nervous Diseases in the Royal University of Graz, Austria. Translated from the German by Charles G. Chaddock, M.D., Assistant Physician, Northern Michigan Asylum. New York: G. P. Putnam's Sons, 1889.

Just at the present time, when hypnotism is being vigorously discussed on every hand, the appearance of the above translation is most appropriate. It is as unwise to deny the reality of hypnotism as it is to believe in its universal application to all persons alike, and for the relief of all sorts of troubles. But strange things are being developed nowadays in regard to mentalization, and as Arago said in 1844, "He who uses the word *impossible*, without the sphere of pure mathematics, is at least careless. As soon as one is concerned with the living organism, caution becomes a duty."

Krafft-Ebing has long been acknowledged an authority upon diseases of the mind, and his name is identified with the progress of knowledge in regard to the phenomena comprehended in the term "insanity." He began the study of the remarkable case which furnishes the subject matter of the present volume free from prejudice, and with a considerable degree of skepticism. The patient was the possessor of three distinctly separate states of consciousness, which had absolutely nothing in common save that they were observed in one and the same person. The experiments were all performed in a manner to positively exclude every chance of simulation. They were many times repeated before medical societies, during clinical lectures, and in the presence of medical men invited to test for themselves the reality of the results.

After a careful perusal of this report, one can acquiesce with the statement of the author that "the greatest skeptic with regard to hypnotism can have no reason to think of fraud in this case." Though such experiments as *suggestion mental*, the use of sealed vials containing various drugs, and clairvoyancy terminated negatively, yet the production of blisters and stigmata, the regulation of the bowels, and the modification of the sensory and motor apparatus by simple suggestion, were no less astonishing than real. The record of these experiments reads like the wildest fiction of the imagination. Yet all the phenomena observed were entirely within the sphere of physiology, and found their analogies in the various hysterical states.

We earnestly commend to the skeptic of hypnotism the careful study of this little book, which has already passed through two German editions. The profession is indebted to Dr. Chaddock for his able translation, as well as the happy thought of publishing so carefully a prepared monograph by a wellknown authority.

Pamphlets.

Eighth Annual Convention of Trustees and Superintendents of the Children's Homes in Ohio, held at Newark, September 17, 18, and 19, 1889. Pp. 64. Keating & Co., Cincinnati, 1889.

Sixteenth Annual Report of the Maternity Hospital, 734 South Tenth Street, Philadelphia, 1889. Press of Patterson & White.

The Medical Digest.

COFFEE is a good vehicle for antipyrin.

THE name of the Hôpital du Midi has been changed to the Hôpital Ricord, in honor of the great man whose twenty-nine years of service gave the hospital its celebrity.

ASSAKY recommends the bi-iodized salicylic acid (*l'acide salicylique bi iodé*), in the treatment of articular rheumatism. The daily dose is twenty-three to sixty grains, and from this he reports very remarkable analgesic and antithermic effects.—*Rev. de Thér.*

PAGLIANO denies that there is any connection between the condition of the heart in typhoid fever and the occurrence of pulmonary accidents, and attributes the latter simply to the advent of Eberth's bacillus, with sundry favoring conditions.—*Revue de Thér.*

THE cholera has subsided in Bagdad, and the latest advices from Persia are more favorable. At the outbreak of the pestilence, the Arabs encamped upon the Euphrates betook themselves to the heights and suffered no stranger to enter their camps, which remained free from the disease.

FOR AURAL FURUNCLE.—

℞.—Menthol . . . . . gr. xv.
Ol. amygdalæ dulcis . . . . . ʒv.
M. S.—Introduce twice daily on borated cotton.
—*Cholewa.*

CHAUVEL affirms that the tolerance of the tissues for leaden bullets is by no means as common as some claim, and is by no means an habitual fact. The immediate extraction of the bullet should not be made the rule, nor should it be neglected when extraction is easy and devoid of danger.—*Revue de Thér.*

MAUREL gives the designation of *hypo-hematosis* to that condition in which the proper balance is not found between the height, weight and thoracic capacity, insufficiency of the latter causing deficient respiratory power. This is to be remedied by respiratory gymnastics.—*Revue de Thérapeutique.*

THERMO-PALPATION. — Thermo-palpation hails from Hungary, where it has been employed for the last year or two in the wards of Prof. Ketli with, it is said, excellent results. It is performed simply by carrying the pulps, or sometimes the backs of the fingers, lightly over the surface of the chest, which is of course, uncovered, and noting the feeling of warmth imparted to the fingers. It will be found that where they pass over solid organs, such as the liver, the temperature is distinctly lower than when they pass over the lungs containing air. If the surface is palpated systematically for temperature, it will be found that the borders of the liver and heart can be accurately marked out. By means of specially constructed thermometers, it is stated that an exceedingly accurate mapping out can be accomplished, and small differences in the condition of the lungs themselves recognized.—*Hospital Gazette.*

An eminent microscopist finds that genuine honey can be readily distinguished from manufactured honey by the microscope, as the former has few or no sugar crystals.

Stoukowenkoff has utilized a new preparation of mercury, for hypodermic injection. His formula:

R.—Oxybenzoate of mercury . . . . . gr. ivss.
Distilled water . . . . . ʒ x.
Chloride of sodium . . . . . gr. ½.
Hydrochlorate of cocaine . . . . . gr. ij.—M.

—*Revue de Thérapeutique.*

Inebriate Asylums.—The following extract is from a recent lecture by Dr. Crothers on this topic:

The first inebriate asylum, at Binghamton, N. Y,, was projected in 1844, but was not opened for patients until 1864, twenty years later. This was owing to the intense and bitter opposition to the theory of disease and curability in special asylums. A good illustration of the historical fact, that every new truth in the progress of the world is greeted with storms of denial and fierce contradiction. The disease of inebriety, and its curability in asylums, was a great event that could not be suppressed by the change of Binghamton to an insane asylum, and today there are over a hundred asylums for inebriates in different parts of the world. Most of these asylums are founded on the fact, now well established, that inebriety is a disease of the brain and nervous system. The use of alcohol in many cases may be only a symptom, in other cases alcohol starts up a train of degeneration which has been inherited, and in all cases there is progressive dissolution of the brain and nervous system, that can easily be reached by medical treatment addressed to the entire system. The removal of alcohol is only one factor in the treatment, the removal of the causes will always be followed by the cessation of the desire for spirits. All treatment and remedies addressed to one state or condition of the body fails for the reason that inebriety is not a local desire, and does not come from the use of alcohol alone. Hence the true principles of treatment must include not only restraint, but limited freedom, together with all means known to science to build up and strengthen the entire system. In the largest and best asylums in this country and Europe all cases are treated as sick and diseased, the duration and degree of restraint is modified to meet the demands of each case, and the general treatment aims to remove the special and general causes which have brought on the disease.

It is a deplorable fact that all inebriate asylums are judged by the statements of incurables who have failed to be benefited by treatment. Judged from these criticisms no inebriate asylum could exist long. Those who are more or less cured in these asylums, disappear and never refer to them, or the benefits they have received. The criticisms of our work have been inspired in many cases by the incurables, while those who have been restored have been silent.

Chloroform and Locomotor Ataxy.—Dr. Thiem, having had to give a patient with slight signs of locomotor ataxy chloroform for the purpose of examining an abdominal tumor, was surprised to notice that as she was being helped from the room, while still somewhat under the influence of the chloroform, she walked with a typical ataxic gait, though this symptom was not ordinarily present. On watching other patients, who were not suffering from this affection, trying to walk while still partially under the influence of the chloroform, Dr. Thiem convinced himself that the peculiar gait only occurred in the subjects of ataxia; in whom the semi-narcotic state brings out the want of coördination in the movements of the legs. The explanation would appear to be that inasmuch as the peculiar gait is not due to any paralysis of the muscles, but only to the want of coördinating power, which is set in action by the control exerted by the muscular sense, and the sense of sight, when, as in the case of a half-chloroformed subject of locomotor ataxy, both the central coördinating apparatus and the peripheral regulating machinery are in a more or less inactive condition, there is a double reason for the existence of the well-known jerking and sliding movements of these patients. It would appear, then, that in doubtful cases of locomotor ataxy some assistance towards a correct diagnosis might sometimes be obtained by partially anæsthetising the patient, and then observing his gait as he walks across the room.—*London Lancet.*

The Physiological Action of Sand Baths.—Dr. N. V. Pariyski has added to the scanty literature of sand baths his observations made upon twenty-five patients in Eupatoria, on the shore of the Black Sea (Crimea, sixty miles W. N. W. of Sevastopol). The patients suffered with various rheumatic complaints. The baths are prepared as follows: At 10 A. M. small heaps of dry sand were made sufficient in number to cover one person. At 11 A. M. the temperature of the sand was about 38–39 R. A hollow was made in the heap, and the patient laid there and covered with the sand, beginning with the lower extremities. The patient remains in the bath without discomfort for nearly half an hour.

Five minutes after the entrance into the sand bath, the patient begins to perspire, and in twenty minutes the whole body is covered with a layer of wet sand half-an-inch thick. The patient is taken out of the bath, the wet sand rubbed off with the aid of dry sand, and he is then washed with warm water.

The following results as to the physiological action were obtained:

1. *Temperature* (in axilla) always rises.

2. *Pulse*, after the bath, was increased on the average by 8.6 beats in a minute.

3. *Respiration* increased, maximum eight in one minute.

4. Amount of exhaustion considerable. The average loss in weight was one pound, the variations being from one-sixth to three and one-half pounds.

—*Vratch.*

Medical News and Miscellany

CARROLLTON, Ill., has had a smallpox quarantine.

SOUTH AFRICA is overcrowded with members of the medical profession.

CAMDEN pays its doctors twenty-five cents for each case of contagious disease reported.

IT is said that an astonishing amount of Jamaica ginger is sold in Maine for drinking purposes.

THE pharmaceutical exhibit at the late Paris Exposition seems to have been practically a failure.

THE *Milwaukee Journal* says that dyspepsia and a broken heart exhibit a wonderful similarity in their surface indications.

COMPRESSED tablets of soda mint in bottles with metallic stoppers become impregnated with the copper in the stoppers, and are thus unsafe for use.

TYPHOID fever is raging to an alarming extent in St. Peter's Orphan Asylum, Newark. The fever is believed to have been caused by bad sewerage.

SOME of the employees of the Bank of Switzerland were lately poisoned by handling bank bills. The bills were colored with Schweinfurt green, an arsenical poison.

THIRTY-FIVE Pennsylvania Railroad conductors listened to a lecture by Dr. Dowling Benjamin in Cooper Hospital, Camden, on "Hemorrhages, Accidents and Emergencies."

A Bridgeboro, N. J., man is walking around with a china doll in his stomach. It is not explained why the toy was put in his mouth, but the swallowing was said to be accidental.

AN epidemic of diphtheria is reported to have broken out at Lancaster, Ohio. More than 100 cases are reported, and the public schools have been closed by order of the Board of Health.

SIXTY children at the Ohio Soldiers' and Sailors' Orphans' Home, at Xenia, Ohio, are in the hospital, suffering from scarlet rash and mild forms of scarlet fever. There are 900 children in the institution.

THE king of the Warramaugas, an Australian tribe, a lad of nineteen, died last month in the Adelaide Hospital. When he became king he refused his royal rank, and had for several years been acting as a guide.

PROF. DIXON states that consumption can be communicated by the use of family tooth brush trays in bath rooms, the brushes thus lying with their bristles in close proximity, affording a medium for the spread of the tubercle germs.

THE Lecture Association of the University of Pennsylvania announce that Miss Amelia B. Edwards has been engaged to deliver a series of six lectures on Egyptology; beginning upon December 4, and continuing on each Wednesday and Saturday. They will be given at Association Hall; the Wednesday lectures at 3.30 P.M., and those on Saturday at 2 P.M.

THE sight of Apollo in red velvet knee breeches will tickle the everlasting gods, says the *Canton News-Democrat*. The literary society of an Ohio Normal School have thus draped the mythical and muscular son of Jupiter and Latona.

DR. KARL KOLLER, of Vienna, who has the credit of discovering cocaine, says that he always administers that drug himself, never prescribing it for a patient, so that the latter cannot secure more of it by merely refilling the prescription.

A VEGETARIAN craze has struck Chicago, a new society having been started to promote this branch of gastronomic science. The movement started among the W. C. T. U., who claim that the eating of meats creates an appetite for strong drink.

SAPOLINI, of Naples, in the treatment of deafness in old age, mops the membrana tympani with a weak oleaginous solution of phosphorus, claiming that this diminishes the opacity of the membrane, increases the circulation, and improves the hearing.

DIPHTHERIA to an alarming extent prevails in Burlington, Iowa, and the country adjacent. There have been several deaths this week, and many children are down with the disease. Precautions are being taken to prevent the spread of the infection.

THE Powers College of Pharmacy, named in honor of the late Thomas H. Powers, and whose incorporators are Dr. Lemuel J. Deal, John E. Cook, Dr. William H. Pancoast, Dr. James Van Buskirk and Dr. Ernest F. Apeldown, has applied for a charter.

MRS. BARTLETT, of Chicago, has discovered a process for developing photographs without the aid of a dark room. She simply exposes the negative to the light for a few minutes, with a sheet of paper clapped on it. The pictures resemble fine etchings. Amateur photographers will appreciate this discovery.

DR. F. O. DONOHUE has been appointed a member of the Syracuse Board of Health by Mayor Kirk and also of the New York State Board by Governor Hill. The appointment has been received with approbation; the Syracuse journals referring to Dr. Donohue in very complimentary terms.

SECRETARY PROBST of the State Board of Health, visited the village of Deunquat, Ohio, and found the members of J. J. Smith's family stricken with smallpox. One little girl had died. Thirteen others have been exposed. The disease is supposed to have been communicated in rags purchased by Mr. Smith, who is a peddler in New Washington, where there were a few cases a year ago.

IT does not require the lively imagination of Jules Verne to conjecture that a time may come when the body will be rendered truly enlightened by means of the electric light. If the open hand, the fingers close together, be held between the eye and bright sunlight or one of Edison's electric lamps, the fingers will appear to be somewhat transparent. We need but wait till this light is many times multiplied in strength, and the body may be rendered so transparent that the functions of life can be studied and disease processes noted with ease.

To Contributors and Correspondents.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, United States Army, from November 19, 1889, to November 30, 1889.

By direction of the Secretary of War, the extension of leave of absence on surgeon's certificate of disability granted Major Leonard Y. Fornig, Surgeon, in S. O. No. 241, October 16, 1889, from this office, is still further extended one month on surgeon's certificate of disability. Par. 3, S. O. 268, Hdqrs. of the Army, A. G. O., November 16, 1889,

MOSELEY, EDWARD B., Captain and Assistant-Surgeon, is relieved from duty at Whipple Barracks, Arizona, to take effect upon the expiration of his present leave of absence, and will report in person to the commanding officer, Fort Clark, Texas, for duty at that station, reporting by letter to the commanding general, Department of Texas. Par. 4, S. O. 268, A. G. O., November 16, 1889.

FISHER, WALTER W. R., Captain and Assistant-Surgeon, is relieved from duty at the Presidio of San Francisco, Cal., and will report in person to the commanding officer, Fort Assinniboine, Montana, for duty at that station, reporting by letter to the commanding general, Department of Dakota. Par. 4, S. O. 268, Hdqrs. of the Army, A. G. O., November 16, 1889.

The leave of absence on surgeon's certificate of disability granted Captain Rudolph G. Ebert, Assistant-Surgeon, in S. O. 109, May 11, 1889, from this office, is extended six months on surgeon's certificate of disability. Par. 13, S. O. 270, Hdqrs. of the Army, A. G. O., November 19, 1889.

By direction of the Secretary of War, the extension of leave of absence granted Captain Valery Havard, Assistant-Surgeon, in S. O. No. 240, Oct. 15, 1889, from this office, is further extended one month. Par. 1, S. O. 272, A. G. O., November 21, 1889.

BALL, R. F., First Lieutenant and Assistant-Surgeon, Fort Riley, Kans., will proceed to Fort Sill, I. T., and report to the commanding officer for temporary duty at that post. Par. 2, S. O. 173, Dept. Mo., Nov. 21, 1889.

By direction of the Secretary of War, Captain James E. Pilcher, Assistant-Surgeon, is relieved from duty at Fort Ward, N. Y. H., and will report in person to the commanding officer, Fort Clark, Texas, for duty at that station, reporting also by letter to the commanding general, Dept. of Texas. Par. 3, S. O. 276, A. G. O., November 26, 1889.

Leave of absence for fifteen days is granted Captain John J. Cochran, Assistant-Surgeon, to commence about December 1, 1889. Par. 3, S. O. 272, Div. Atlantic, Nov. 27, 1889.

Changes in the Medical Corps of the United States Navy for the week ending November 30, 1889.

GUNNELL, F. M., Medical Director. Placed on the Retired List, November 27, 1889.

GAINES, J. H., Surgeon. Ordered to duty at Army and Navy Hospital, Hot Springs, Ark.

Medical Index.

A weekly list of the more important and practical articles appearing in the contemporary foreign and domestic medical journals.

Alcohol in puerperal fever, Martin. An. of Gyn., Nov., 1889.

Antiseptic midwifery, McRae. Atlanta Med. and Surg. Jour., Oct., Nov., 1889.

Artificial urinary canals, formation of, Wishard. Ind. Med. Jour., Nov., 1889.

Abdominal section, Hoffman. An. of Gyn., Oct., 1889.

An address delivered before the Northumberland and Durham Medical Society, Tait. Med. News, Nov. 9, 1889.

Beginners of Disease, Pope. Med. Press, Oct. 9, 1889.

Beiträge zur Aetiologie und Therapie der primären Pleuritis, Eugster. Deut. Arch., Oct., 1889.

Blut Körperchenzählungen und Hämoglobulin bestimmungen bei Kindern, Stierlen. *Ibid.*

Bakteriologisches über Otitis media, Levy u. Schrader. Arch. f. Exp. Path., Oct., 1889.

Blenorrhœa neonatorum, Williams. N. W. Lancet, Nov. 15, 1889.

Color blindness, Eldridge-Green. Med. Press, Oct. 23, 1889.

Concentrated solution of magnesium sulphate as an enema, Watkins. Md. Med. Jour., Nov. 9, 1889.

Constipation in childhood following diarrhœa, Vernon. Am. Pract. and News, Nov. 9, 1889.

Cartwright lecture, Billings. Med. News, Nov. 23, 1889.

Chronic endometritis and chronic vaginitis, Mundé. An. of Gyn., Nov., 1889.

Congenital dislocations of the hip, Evans. Med. News, Nov. 16, 1889.

Drei Fälle von Pericolitis, Windscheid. Deut. Arch., Oct., 1889.

Drink-craving, nature and management, Bird. Va. Med. Mo., Nov., 1889.

Diphtheria at high altitudes, Turner. Med. News, Nov. 9, 1889.

GRANULAR LIDS—ENUCLEATION OF BALL.[1]

BY PETER D. KEYSER, M.D.,
Professor of Ophthalmology in the Medico-Chirurgical College, and Surgeon to the Wills Eye Hospital, Philadelphia.
(Reported for the TIMES AND REGISTER)

GENTLEMEN: Of all the affections of the conjunctiva, there is none so troublesome, as well as vexatious, to both physician and patient (and I might say the family and friends of the latter) as that form called granular lids—conjunctivitis granulosa. In speaking of this form of disease I do not mean catarrhal conjunctivitis, which patients frequently call "*granulated eyelids*," whether from their own idea of the trouble, or from information often expressed as being received from a physician, but that form which shows conclusively the well-known appearance of true follicular enlargements or excrescences on the conjunctiva.

In looking over the field in relation to this disease, there are generally three forms described in the text-books—the *papillary*, in which the papillæ of the conjunctiva only are greatly enlarged, which is an early stage of the inflammation; the *follicular*, in which the lymph follicles have become enlarged by the inflammatory action passing back into the deeper stroma of the tissues and affecting them; and the form called the *mixed*, in which both the papillary and follicular enlargements are clearly defined. The last form is found in almost all cases that have been of some duration under considerable inflammatory activity, and is really the form most generally seen.

The three cases I present to you to-day are typical ones of the three forms mentioned. You will see, when I turn these lids, that the papillæ of the conjunctiva are alone enlarged. They appear in little sharp-pointed projections. This second one, the conjunctiva looks as if covered with frog spawn—round yellowish-red follicles covering the whole surface. In the third case, on close examination there can be seen some follicles which have fine papillary prominences between them.

Conjunctivitis granulosa arises from many causes, among which may be named, first, contagion, then neglected or badly-treated catarrhal or simple conjunctivitis; and it is also a sequel at times from purulent conjunctivitis, due to careless treatment. The origin of the inflammation is claimed by many to be mycosis. But let it be from whatever origin, it is nevertheless a tedious disease, at times painful, and also dangerous to sight from extension of the inflammation to the cornea. The greatest percentage of blindness arises from this disease in most all countries, especially in sandy lands—as in Egypt, and the Western States of this country. I am also informed that it is very prevalent in China among the lower classes of people.

The treatment requires great judgment and patience on the part of the physician, and very much of the latter on the part of the patient. The case must be carefully watched, to notice changes and any complications. Remedies innumerable have, from time to time, been advocated and found by many excellent, while in other hands not so sucess-

[1] Delivered at the College, November 22, 1889.

ful. This may in part be accounted for by the lack of observation and discrimination in the form and character of the disease at the time of treatment. Astringents have been the main reliance, and sulphate of copper was the sovereign remedy for a long while, and of every eye, no matter what the form or grade of inflammation, the conjunctiva was touched with the crystal of *blue stone*. Then came the mitigated stick (1 part nitrate of silver to 2 or 3 parts nitrate of potash) as advocated by Von Graefe, in Berlin, while the Vienna school was brushing the conjunctiva with a solution of nitrate of silver, gr. x–℥j.

Then came other remedies, as tannin, hydrastis, yellow oxide of hydrargyrum, etc., all of which have their advocates and are excellent in some cases; but failing with all these brought out operative treatment; the cutting out the fold of the conjunctiva above the tarsal part, as well as shaving off the granulations; then was introduced the inoculation of pus from a case of purulent conjunctivitis neonatorum, so as to set up a severe inflammation to effect the absorption of the granulations on its recession. The pus instillation in the eye being considered too dangerous for the cornea, the Jequirity treatment was recommended by De Wecker, of Paris, and I must say has given some brilliant results in my hands. This treatment consists in the instillation of a 2 per cent. aqueous solution of Jequirity beans three or four times daily in the eyes, for one or two days. It creates a very painful and severe inflammation, which soon passes away under simple treatment of cold water cloths applied over the eye, and a collyrium of 10 grs. boric acid to ℥j aqua destillata.

Lately the use of bichloride of mercury, in solution 1-500, instilled in the eye two to three times daily, and a stronger (1-200) solution brushed over the conjunctiva once or twice a week, has come into favorable notice.

Taking all the remedies recommended, every one has a certain amount of virtue, and if applied when the conjunctiva is in just the condition for its use, there will be an improvement. But unfortunately, this improvement does not always continue, and relapses occur. I have found, after years of experience, that every remedy—if continued too long—loses its virtue, and before the reaction takes place should be discontinued, at least for a while, and another used. In this way many very obstinate cases may be cured.

The bichloride of mercury solution 1-1000 has worked wonders in some chronic forms when there was great inflammation; while those of 1-500 irritated too much.

There is one stage or change in the conjunctiva that has given more trouble to cure than any, but which fortunately, is not very frequent in its appearance, and over which nothing has acted successfully in my hands until lately. This form is that in which the inflammation in the eye has, as a general thing, passed all—or nearly all—away, there remaining a slight irritation and weeping, and at times a thin, gelatinous discharge, but seldom any gluing of the lids. On turning the upper lid, isolated or small collections of yellowish-white, round nodules are seen scattered over the tarsal part of the conjunctiva, while the fold is perfectly free and smooth. These granulations are prominent, and have a hard, cartilaginous feeling on passing the finger, especially the nail, over them.

None of the well-known remedies appear to have any effect in reducing them. Cauterizing or cutting them off does not remove them, and often leaves the conjunctiva worse, in so far that cicatrization and scars may be left, which are irritating to the cornea. Even the instillation of the powder or a solution of the Jequirity bean has not been successful in causing their absorption. But lately the idea suggested itself to me to try to rasp them off by the use of pumice stone. So this summer I took a well-marked case, of eight years standing, in a lad twelve years old, a son of an officer of the regular army, who had been through the usual routine in several cities of the West and East, and in the army posts without success, and determined to try it. Every day for a few days, I turned the upper lid and rubbed well over the tops of the hard cartilaginous granulations with a flat piece of pumice stone. This caused considerable pain during the rubbing, and created quite a congestion of the tissue with slight hemorrhage. After the daily rasping for the few days, it was made three times the next week, then twice a week, with the most wonderful results. In six weeks' time the granulations were completely rasped down, and the whole conjunctiva was smooth and in a healthy condition. After every rasping the conjunctiva was inflamed and sore for ten to twelve hours, but passed away on the application of hot water cloths. The eyes were kept clean all the time by the use of a collyrium of boric acid, gr. x–℥j, and the lids were anointed with an ointment of yellow oxide of mercury, gr. ½, in lanoline ʒj. The case has kept well ever since, and the patient is in as good condition as can be. I would therefore recommend to you this treatment if any such cases should come under your notice.

This other case comes before us with the history that ten days ago, while striking a hammer on a cold chisel to force up a hoop on a barrel, something flew into his right eye and it has been blind ever since, as well as somewhat inflamed, although the inflammation has been kept subdued by constant applications of cold water cloths. Upon examining the eye, a horizontal incision is seen, a little back of the inner line of the cornea, extending across the sclerotica and through the ciliary body. The anterior chamber is free, but the vitreous chamber is completely filled with blood, so that no illumination of the fundus can be made. This great hemorrhage in the ball shows clearly that the ciliary process has been lacerated. Being a very vascular part of the eye it bleeds very readily on injury.

The patient thinks that there is nothing in the eye, but the character of the incision, with the great hemorrhage in the ball, proves distinctly to my mind that a splinter of steel has gone through into the vitreous body. This kind of an injury is of frequent occurrence among machinists, and others who drive a hammer on a chisel or rivet—such as boiler makers.

In cases of this kind it is impossible to see where the foreign body is in the eye for its removal by a magnet. Pieces of steel or iron often pass through the cornea and sclerotica without causing the least hemorrhage. In such cases it is not so difficult to see them with the ophthalmoscope and remove them by the electro magnet. But in this case the hemorrhage is so thick that it is impossible to attempt to look for it, and therefore the safest and best treatment is to enucleate the eyeball, to remove any danger of sympathetic ophthalmia in the other.

The enucleation of an eyeball is not a difficult operation if you know thoroughly the anatomy of the parts and have some dexterity in the handling of delicate instruments, and, like most everything else, it is quite easy when you know how to do it. It is a painful as well as delicate operation, and before the introduction of cocaine as a local anæsthetic, it was necessary to thoroughly etherize the patient; but now, under the use of 4 to 6 per cent. solution of cocaine, local anæsthesia can be acquired that will permit in most cases, most of the operation to be performed; and then, under very little ether, the completion can be very quickly and readily carried out.

Having instilled the cocaine solution several times into the eye, the speculum is introduced to widely separate the lids, then, with the forceps and scissors, the bulbar conjunctiva is separated around close to the cornea, then each rectus muscle can be taken up either by the forceps (as you see I do it) or the strabismus hook, and the attachment at the sclerotic cut loose by the same scissors in your hand. After separating all the recti, then pass the hook under the two oblique muscles and loosen them. Now that all the muscular attachments are free, the only thing really holding the ball in place is the optic nerve. Before cutting through it and the ciliary nerves and vessels which pass into the eye near the optic nerve, the patient should be given some ether to breathe. As soon as the first stage of action of the ether is noticed—that is, the quiet stage, or a short loss of consciousness, before that of excitement comes on—the ball should be rolled to one side by either the forceps or a hook, the scissors passed in back of the ball, blades opened, and with one cut (if possible) the optic and ciliary nerves severed. The ball can then be lifted out and any minor adhesions cut loose.

Considerable hemorrhage takes place, but can generally be readily controlled by pressure and applications of hot water. Formerly cold water—and even ice—was used, but since the discovery of the styptic action of hot water, it is found to be preferable and acts more effectively.

In some cases the conjunctiva may be brought together by sutures, but really it is unnecessary, as the whole thing heals up without any, or very little after-inflammatory action. After the hemorrhage has been stopped, apply a firm compress bandage over the eye, to prevent any secondary bleeding taking place.

Having removed the ball, we will now cut it through in half, to see if a foreign body is contained therein. You see how the posterior part, or vitreous chamber, is filled with coagulated blood. Now, throwing this out and feeling carefully, I come across a hard sharp substance which, you see, I present to you as a small, triangular, wedge-shaped piece of steel.

RUPTURE OF THE KIDNEY—CARCINOMA—PYO-NEPHROSIS.[1]

By CHARLES McBURNEY, M.D.,

Robert A. Sands, Acting House Surgeon.

(Reported by Dr. K. B. Page, M.D.)

GENTLEMEN:—The first case I shall operate on to-day is one of tumor of the kidney.

Of the exact nature of the tumor we are uncertain. By exploration with a hollow needle I have found pus, and this in connection with the other symptoms, has led me to form the opinion that this is a case of pyo-nephrosis, abscess of the kidney.

The man gives the following history: Aged thirty-nine, married, a rubber-hose maker, has complained for one and a half years of constant pain in right side of abdomen, has had nausea and vomiting, and at times slight jaundice; weight averages about one hundred and seventy-eight pounds, bowels are costive, there is no ascites; examination of urine reveals no albumen, sugar or casts, sp. gr. 10–20, acid.

In the month of February, of this year, a distinguished consultant of this city saw the case and made the diagnosis of tumor of the kidney, probably carcinoma.

Another well-known gentleman diagnosed the case as distension of the gall bladder with occlusion of the cystic duct, and ascribed the jaundice to this. These opinions are mentioned to illustrate the difficulties of diagnosis in the early stages of pyo-nephrosis.

The patient was brought to me by Dr. W. B. Clark, of this city, for treatment.

On admission, a somewhat nodular tumor could be made out by palpation, occupying nearly the whole right abdominal half, extending inwards to the umbilicus and downwards to the iliac crest.

The examination of urine was practically negative, but a trace of albumen and only one cast were found.

Revising the history and notes of examination we find we have the history of a growth in the right loin, in the location of the kidney. The urinary symptoms are negative, probably because the kidney tissue is totally destroyed, and the ureter occluded so that none of the contents of the tumor can get into the bladder. The man has lost, then gained, flesh, at various times, and his general appearance makes it extremely doubtful that he has carcinoma of *any* organ.

With a sterilized exploring needle I puncture the tumor from behind—as you see I obtain pus. Making an incision in the loin, down to the tumor, and protecting the edges of the fresh wound with sponges, I incise it, giving vent to pus. Introducing my finger into the cavity, I find that while of considerable size, it does not constitute the whole tumor, therefore, it is multilocular. Incising the second compartment, I give exit to pus in large quantities. This loculus is five or six times the size of the first.

[1] Delivered in the Roosevelt Hospital, New York.

We will thoroughly irrigate these cavities with Thiersch's solution, insert drainage tubes into either cavity, sew them in place for safety, and sew the edges of the operation wound together around them.

A permanent fistula will probably result with the continuance of a persistent discharge, and in some weeks, when the sac is thoroughly contracted, I will do a second operation for removal of the sac.

I do not consider it advisable to do a nephrectomy in this case, as the large size of the tumor would render this dangerous; but the operation I have indicated is practically without danger.

This operation makes it clear then that there was no neoplasm of the kidney; it was a case of abscess of the kidney. In my examination of the interior of the sacs, I did not find a calculus nor any of the amorphous material, so that it is impossible to state the origin of the pyo-nephrosis, whether calculus, blood-clot, or other body.

The second operation is also one for a lesion of the kidney; it is a case of

TRAUMATIC RUPTURE OF THE KIDNEY.

This woman, aged twenty-seven, M. III para, was brought to the hospital in the ambulance at 10 A.M., October 28, with the history of a fall out of the third story window, a height of from forty to fifty feet. She was in a state of most profound shock—temperature 97° F., pulse 106, respiration 28, and very shallow; vomited blood. It was only by the skill and assiduous devotion of the house staff that she rallied; her condition was then too critical to admit of examination. The next day she had improved a trifle. On careful examination we could find no broken bones as results of this great fall, but the abdomen was tender and swollen, and she had the appearance of a patient who had a severe internal injury, so that rupture of the intestines was suspected. After three days she began to improve slowly, and there was still no clear evidence to indicate the particular organ injured. At the commencement of this month she began to vomit and have some fever. A tumor was then noticed to be forming in the loin, which was opened on the 6th inst. by Dr. Hartley. Her condition was still so dangerous that ether could not be used, so the operation was made under cocaine anæsthesia. The incision of the tumor gave exit to a large quantity of pus, which our house surgeon describes in terms more forcible than elegant, yet strictly appropriate, as "highly stinking ammoniacal pus." The cavity was drained.

As she has had stools, per rectum, rupture of the intestine may be excluded, and, taking the symptoms into consideration, I believe we have a clear case of rupture of the kidney. I believe that at first the rupture was situate in the cortical region, that the opening into the pelvis and extravasation of urine was secondary. There is a large sac in the right loin, and you see the drainage tube of the first operation. The patient's condition has heretofore been such as absolutely prohibited a thorough examination of the abscess cavity, but I shall now make an oblique incision in the loin at the lower part of the sac, examine thoroughly, and determine the exact condition of the kidney. The patient's condition is too poor to do a nephrectomy, so that, as in the previous case, I shall thoroughly drain and await further improvement of her condition for the second operation, if one is called for.

The cavity which I have opened by this incision is of great size, my finger passing downward to the iliac fossæ. Passing my finger over the surface of the kidney, I find it smooth, save at the lower part, where I feel a rough cleft, covered with granulations. I cannot positively state where the rupture is, but this is probably the point. A drainage tube will be sewed in, and the cavity packed with gauze.

HEREDITARY CARCINOMA.

My third case gives a very interesting history, illustrating the influence of heredity in the occurrence of carcinoma:

This woman's father died of epithelioma of the lip. An aunt on the paternal side had cancer of the womb; another aunt had recurrent tumor of the breast. Her mother, shortly before death, had a growing tumor in the right iliac region, and a sister is thought to have had cancer of the stomach. A very remarkable history.

The patient before us, aged thirty-nine, III para, noticed for the first time two years ago, a tumor the size of a hickory nut in the right breast. The growth increased slowly until four months ago, then grew more rapidly; but its greatest increase has been in the past two months. There have been severe shooting pains in the breast.

The tumor is now about two inches in diameter; painful on pressure. The nipple and skin over the growth are not adherent, and part of the breast is apparently healthy. Slightly enlarged glands can be felt in the axilla. The case is undoubtedly one of scirrhous disease of the breast, and is now in favorable condition for operation.

I shall make an incision starting in the axilla, extending inward towards the median line, encircling the breast, and returning to the axilla. The growth has not infiltrated the sublying muscles, so that we easily dissect it off with the sheath of the muscle.

Having done this, and cleaned out the axilla we unite the wound by continuous suture, introducing catgut drains. The whole wound will be united; but we will make another opening in the skin of the axilla to insert a rubber drainage tube. At the expiration of three or four days this will be removed. As this operation has been practically aseptic, we should have immediate union.

ANTIPYRIN IN LABOR.—Antipyrin for labor pains was administered by Lelligman in Winckel's clinic, with noteworthy effect in fourteen cases. The pains were not only relieved, but the intervals became longer and the patient more calm. In some cases labor was interrupted, in one it became more energetic. One to ten hypodermic syringefuls of 50 per cent. solution, about 7½ grs. or 30 grains per enema, was used, beginning with the latter. The effect lasts two hours.

—*Munich. Med. Woch.*

Original Articles.

REVIEW OF PROGRESS IN MEDICAL AND SURGICAL ELECTRICITY.

By WILLIAM R. D. BLACKWOOD, M.D.,
PHILADELPHIA.

ELECTROLYSIS IN ANGIOMA OR NÆVI.

DR. MARSHALL, of Nottingham, calls attention in Braithwaite to electricity in nævi, and urges its use to prevent scarring. He prefers the positive pole as leaving little, if any, of the brown discoloration due to the negative. Low currents are employed—thirty milliamperes.

Dr. Duncan, of Edinburg, relates nine cases of angioma of unusual interest treated by galvanism successfully. Three operations sufficed to cure a nævus the size and shape of a Jaffa orange, situated behind the ear of a puny child, three months old.

Another involving the foot completely through from dorsum to sole, including the fourth metatarsal bone, in a child eight months old, was almost entirely removed by six applications.

A cavernous angioma at the bend of the elbow, in a lady nineteen years old, which had sloughed and threatened sepsis, was cured by electrolysis in a year, the applications being infrequent. A pulsating aneurism followed a wound by an umbrella rib in the eyelid. Protrusion of the eye and diplopia ensued. Thirty milliamperes for seventeen minutes, four times at intervals of a week, removed the difficulty. Another instance of exophthalmus, due to injury, was similarly cured. Two cases of cirsoid aneurism of the scalp were also reported as removed by electrolysis.

Both gentlemen refer to the difficulty of insulating the needles. My own plan is to coat them with a thin layer of the ordinary liquid rubber-cement used for repairing tubing on bulbs. Dip the needle in, let it drain, dry it without artificial heat, suspending it point downward. When required for use scrape off the quarter inch nearest the point, rub till it shines, and you have everything lovely. I use the same plan for bougies and urethral electrodes generally, but the coating should be thicker. Rotate the needles before withdrawal, and if the negative be used for desirable purposes, reverse the current for a moment, when loosening will occur.

Electricity in Uterine Fibroids.—Lucas-Championniere is of the opinion (London *Med. Recorder*) that fibroids near the menopause are the only ones requiring electrolysis. He believes that "decongestion," rather than actual shrinking of tissue elements proper is attained, and he urges frequent changes of polarity, with not over sixty milliamperes for ten minutes. Doubtless his results are as he says, but if he will try the effect of putting in more coulombs, in the same time, he will get the positive reduction of the tumor aside from exsanguination. The fundamental idea is galvano-caustic electrolysis from the negative alone.

Faradism in Enuresis.—Guyon has long ago employed electricity in this complaint in young boys, and Janvier in girls also, but it has not been tried in cases after puberty, except to a limited extent. Bransford Lewis recently used it in the case of a girl fifteen years old, in whom the nocturnal discharge ceased after the first treatment. One pole was applied in the urethra, the other on the thigh. Eleven *séances* were held to clinch matters.

Large Fibroid Polypus.—Dr. A. L. Smith (in the London *Med. Recorder*) describes a pear shaped tumor four inches in length, attached by a broad pedicle to the uterus, which Brosseau deemed not removable by section, owing to the exhaustion of the woman by hemorrhage. The large size of the pedicle was another disadvantage to a cutting operation. She was successfully treated by Dr. Lapthorn Smith by galvano-puncture in eight sittings. Fifty milliamperes were used at each application. The mass shrank to nothing.

Electricity in Pelvic Pain.—The successful employment of galvanism, thus, in the relief of pelvic pain must be based upon: 1st, the varying effects of the poles from a slight irritant to a violent acid alkaline caustic; 2d, the effect of inter-polar electrolysis, which promotes rapid absorption; and 3d, its general trophic effect, with general improvement of nutrition.

Electricity, unlike all other applications upon which the gynæcologist has learned to depend, with varying success, has something more than a surface effect. The amount of electricity that passes through a hyperplastic ovary, is the same that traverses the electrodes between which it lies. If the remedy is of value at all, that ovary must get the benefit of its effect just as certainly as though the sponges of the electrodes were in actual contact with it. With electricity we have a remedy, then, with which we can make local application to the most deeply situated organs.

1. Do not advise the removal of an ovary for persistent pain, until galvanism has been systematically and thoroughly applied, if any of the following conditions are suspected as a cause: (*a*) chronic ovaritis, either with or without hypertrophy; (*b*) where inflammatory deposits, either with or without adhesions, surround one or both organs; (*c*) ovarian neuralgia; (*d*) all pain coincident with menstruation; (*e*) in all cases of ovarian pain not known to be the result of active, acute inflammation, septic or specific inflammation, and cystic tumors.

2. Galvanism is a sure remedy for all pain resulting from tubal diseases, except when septic or specific inflammation is the cause, or the presence of pus is demonstrated.

3. Galvanism is positively indicated in dysmenorrhœa or other pelvic pain, when a result of chronic metritis; a result of hyperplastic enlargement of the uterus; or a result of fibrous or other non-malignant growths of the uterus.

4. Galvanism is emphatically indicated in pelvic pain when a result of old pelvic exudates of all kinds, provided acute inflammatory action is absent and the presence of pus is not suspected or demonstrated.

5. Galvanism is indicated in the pelvic pains arising from reflex disturbances or hystero-neuroses the condition well defined by Engelmann as "a phenomenon which stimulates a morbid condition in an organ that is anatomically in a healthy state."

6. Galvanism is indicated in dysmenorrhœa, when the result of cervical lacerations with unyielding cicatrized plugs; when the result of cervical endometritis or uterine vegetation.—*Martin, N. A. Pract.*

Faradism in Dilatation of the Stomach.—Baraduc holds that only functional cases dependent on atony of the solar plexus are suitable for electrical treatment. One pole is applied over the epigastrium, and the other passed through an œsophageal tube, the stomach being previously dilated somewhat with water. The rheophore is a short copper stem, and it is held *inside* the tube, near its distal extremity. Relief is rapid. Contraction is assured by quantity currents—relief of pain by tension.

Dujardin-Beaumetz, Bardet and Erb, recommend external applications, but these are not nearly so efficacious as the direct method.

Electricity in Intestinal Obstruction.—Dr. Lavat advocates the use of galvanic electrization in all cases of intestinal obstruction, and reports six successes from it. Sometimes more than one application is necessary to bring about a movement.

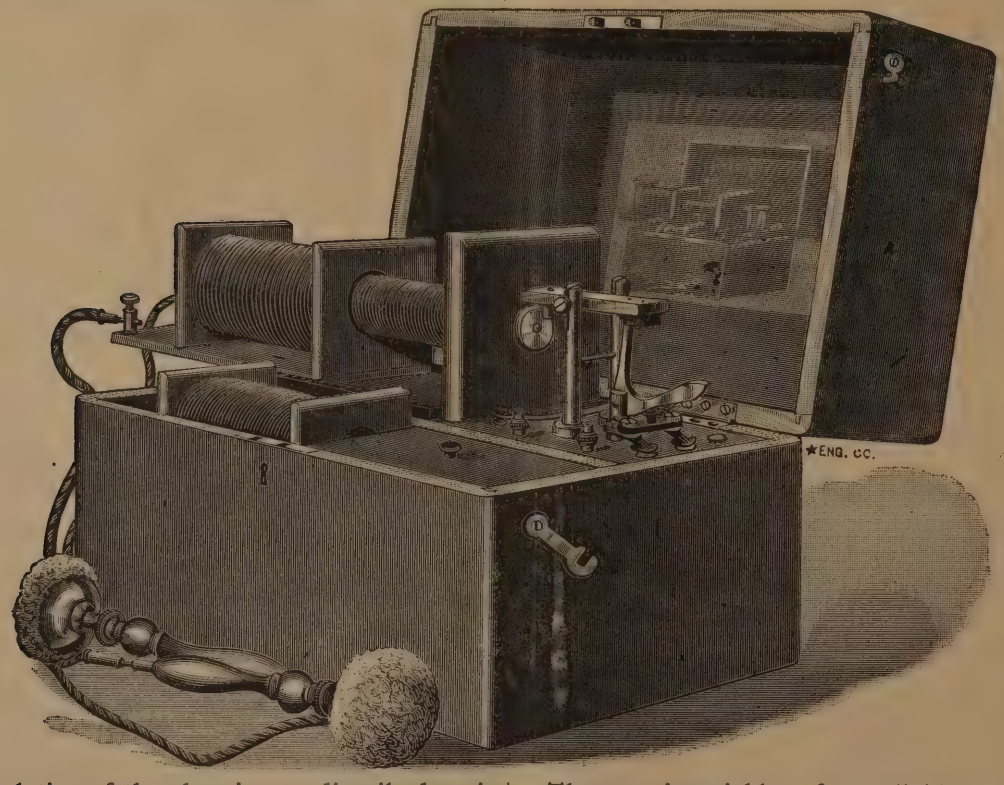
Electrical Stimulation in Apnœa during Anæsthesia.—Drs. Hare and Martin advocate the use of the electric brush to the epigastrium in this condition, the other pole being applied to the base of the rib, not on the pneumogastric in the neck. Rapidly interrupted currents are used. They claim danger as existing when stimulation of the phrenic as ordinarily done is tried, because of the closeness of the cardiac inhibitory nerves to the latter. In noticing direct stimulation of the heart by œsophageal electrodes some time ago in one of these reviews, I called attention to this danger. There is, however, little risk in using Faradism in the ordinary way, and it is equally serviceable as galvanism in all the instances, such as failing respiration from opium poisoning, and the like.

Electrolysis in Surgery.—Newman, of New York, recently adverted to the principles which should govern this matter, before the Ontario Medical Association in Toronto, Canada. The successful method involves the following:

1. Using the correct strength of the electric current.
2. Applying the respective poles in the right place.
3. Selecting the size, shape and material of the electrode.
4. Regulating the *duration* and intervals of seances.

He goes on to state that for the purpose of electrolysis a galvanic current only can be used, and that the negative pole should be selected for the immediate destruction of tumors and strictures, its action more closely approximating that of a caustic alkali, and leaving a cicatrix which is soft and not retractile.

His paper concludes with a review of the practical uses to which electricity has been put in the different branches of surgery. Aneurism, varicocele, hernia, hydrocele, hemorrhoids, tumors of various kinds, malignant and benignant, goitre, enlargement of glands, strictures of the œsophagus, rectum and urethra, atresia vaginæ, opacities of the cornea, extra-uterine pregnancy, endometritis and the various uterine displacements, are but a few of the many affections which he mentions as having been successfully treated by electricity.



The use invariably of a reliable galvanometer should have been demonstrated, for in ordinary practice too many physicians rely upon the feelings of either the patients or themselves as to the power employed. I have known five milliamperes to be used in an attempt to check uterine hemorrhage from papilloma when from seventy-five to one hundred and fifty were indicated. You can't *feel* low currents by the hands.

NEW OR IMPROVED APPARATUS.

New Faradic Machine.—Messrs. Stevens & Son of the Toronto Galvanic Works (Canada) have devised a battery comprising differential coils from which a number of varying currents are obtainable. The apparatus is powerful and compact; it is thoroughly well made, and reliable, besides being economical in operation, and cheap in first cost. The rheotome is novel and effective, and the different currents are smooth yet strong. The curious notions held by many physicians that variable secondaries are of no practical use is dispelled by experiment with a machine built as this is, were the employment of converters in electric lighting not sufficient proof of the transforming of high pressure (voltage) currents with small quantity (amperage) into large quantity currents under light pressure, and *vice-versa*. The cut (see page 774) shows the appearance of the machine, and further information can be had from the makers on request.

An Abdominal Clay Electrode.—Dr. Frank R. Glasgow has devised an electrode which is a shallow round vessel made of leather. The bottom is a round piece of leather of moderate thickness; the sides are formed of a strip of one to two inches in width. A round hole is cut in the bottom in order to allow the connection for the wire of the leaden or copper plate to protrude. The plate fits loosely in the bottom; the top edge of the sides of the cup are turned over and sewed, so as to form a rim.

The cup is filled with soft, moist clay, and on the surface extending over the leather is laid one thickness of blotting paper. This keeps all fine particles of clay from sifting through. Over the whole and extending down the sides is drawn a piece of cotton cloth, which is held fast by a rubber band sprung over it. A little warm water is poured over the surface and the electrode is ready for use.

After using this on one patient, the cloth can be rinsed out and replaced; the clay and filter paper remain *in situ*. This clay will remain moist indefinitely if a piece of rubber cloth is placed over the top. The electrode can be warmed by laying it in hot water or placing it over boiling water. The electrode is not very pliable and is heavy—both good qualities in the great majority of cases. The distance the current has to pass is equal in all parts of the electrode, and even if this were not strictly true, the resistance is so little that it is practically so.

Protection from Strong Currents.—As the low pressure circuits of the incandescent lighting systems are being employed by many neurologists in our large cities, a method of avoiding accidental crosses is valuable in saving office apparatus, and the National Electric Protective Company of New York has devised an instrument for this purpose.

The protector is a small instrument (6 x 2½ inches), with a single electro-magnet wound with coarse wire to a very low resistance (about one-tenth of an ohm), and is placed in the circuit of the telephone or any electric system. It remains quiescent until the wire or circuit becomes abnormally charged by atmospheric, electric light or other strong current, when the magnet attracts the armature, and automatically grounds or shunts the excess as long as the excessive current remains. When the excessive current ceases or is removed, the protector readjusts itself automatically and restores the circuit to its normal condition.

FACIAL ERYSIPELAS COMPLICATING A VARICOSE ULCER OF THE FOOT.

By W. A. N. DORLAND, A.M., M.D.,
Chief of Gynæcological Clinic, Medico-Chirurgical College, Philadelphia.

THE case of which the following are the notes was one of such great interest to the writer that it has seemed well to him to present, in the present form, the two or three points which were deemed worthy of special notice, in the hope that further suggestions might be elicited upon the subject.

About the middle of October he was called upon to attend a stout, robust woman, fifty-two years of age, who was suffering from a large ulcer, involving the whole dorsum of the right foot, and extending to about two inches above the ankle joint. The woman stated that it had commenced with the bursting of a dilated vein at a spot just below the external malleolus, from which initial point it had rapidly spread, until it had reached the dimensions it then had. Upon examination, numerous varicose veins of considerable size were found extending up the limb to the knee. The ulcer was healthy in appearance, and presented no edge of induration. Attempts at strapping proving painful, a simple dressing of iodoform was made, followed by the tight application of a roller bandage. Under this treatment granulation progressed rapidly, until the morning of Monday, the 4th of November, when he was hastily summoned, and found the patient laboring under considerable fever, which was subsequent to a chill. The whole surface of the ulcer, which till then had been discharging freely, was dry, glazed, hot, and painful, and strongly erysipelatous in appearance, while under the left eye was a suspicious looking, dark-red spot. Upon investigation, it was found that the patient had left her room on the previous day, and had remained down stairs for three hours, in attendance upon her household duties. She was in great distress about her present condition, fearing the onset of an attack of erysipelas. She stated that one paternal aunt had suffered with erysipelas, that her sister had died of the meningeal form, that another sister had had a severe attack of the disease, from which she had recovered, while she herself had passed through two previous attacks—the first appearing in her leg, and the last a slight attack in her face.

Incision of the erysipelatous patch in her limb not being permitted, much relief was afforded by the application of cloths wrung out of hot water. The spot under the eye rapidly assumed an erysipelatous character, and invaded the surrounding surface, closing both eyes, and involving most of the forehead—stopping, however, at the border of the hair. She was placed upon full doses of quinine, together with thirty drops of the tincture of the chloride of iron, every two hours, and upon tablespoonful doses of Wyeth's preparation of beef, wine, and iron after

meals. Her diet consisted of chicken broth, milk toast, and buttermilk. Under this plan of treatment her condition rapidly improved, and by the evening of Friday, the 8th, the swelling had almost entirely disappeared, while there remained but a small area of redness where the disease had first appeared.

The intense itching of the face during convalescence was relieved by bathing the spot in warm water three or four times daily, following each lotion by an inunction of vaseline. In the meanwhile, the ulcer in the foot had healed entirely under rest and the simple application of powdered oxide of zinc. The patient is now about and enjoying her usual state of health.

There are three facts in the history of this case which seem to be possessed of special interest. The first of these was the occurrence of the sudden metastasis to the face; the second, the presence of a marked hereditary feature; the third, the portion of the face first involved in the erysipelatous process; and to these might be added a fourth, namely, the prompt response of the disease to treatment.

Passing over the first of these points as being but an interesting phenomenon, the occurrence of which has been frequently noted in this affection, earnest attention would be called to a consideration of the second point, namely, the hereditary feature of the case. After an extended review of the literature of erysipelas, nothing whatever has been found referring to heredity as taking any part in the disease; and yet the history of our case points strongly to the existence of such a factor. The fact that her aunt had been afflicted with the disease, that one sister died of the meningeal form, that another sister suffered from a severe attack of facial erysipelas, and that the patient herself has had three attacks—two involving the face—is proof positive that some special predisposition (might we call it the erysipelatous diathesis?) existed in the family. At any rate, the matter is worthy of further investigation.

In a pamphlet published in 1858, Dr. Bird[1] records that in forty-nine cases of facial erysipelas occurring in females, in ten only, or but $19\frac{6}{10}$ per cent., did the disease begin upon the left side of the face, by far the larger proportion occurring upon the opposite side. A somewhat larger proportion existed in a series of twenty-seven cases occurring in males, when in ten, or $29\frac{4}{10}$ per cent. of the cases, the disease began upon the left side. This adds somewhat to the interest of the case in question, the process here commencing under the left eye.

When we consider that in five days the disease had run its course to complete recovery in our present patient, further comment is unnecessary as regards the last point of interest mentioned.

Hydrotherapeutics.

A PLEA FOR THE PRACTICAL UTILIZATION OF HYDROTHERAPY.[1]

By SIMON BARUCH, M.D.,
Attending Physician New York Juvenile Asylum and Manhattan General Hospital.

[Continued from page 755.]

WHAT is the aggregate result of the effects referred to—the effect upon the cardiac action, the vascular tension, the quality of the blood and its distribution, the effect upon heat production and elimination, and upon the nervous system? Surely an agency which is capable of impressing such modifications upon vital processes as physiological experiment has exactly demonstrated with regard to hydrotherapy, must exercise a paramount influence upon nutrition, tissue changes, the secretions, and excretions, those processes which depend upon the circulation and innervation, and heat production and elimination for their execution.

As has been well said nine years ago by Dr. Mary Putnam Jacobi (p. 59), in the only scientific work on hydrotherapy produced in this country: "The increased production of heat, determined by stimulation of the heat regulating apparatus, irrespective of the amount of heat abstracted by the cold, involves functional activity: 1. In the sensitive afferent nerves. 2. In one or more parts of the nerve centers. 3. In centrifugal nerve fibers of some kind terminating in muscles. 4. In the muscles where are performed the chemical processes involved in the production of the excess of heat. Thus the organism is induced to perform a definite and not inconsiderable amount of work. On this account its nervo-muscular tissues—or a large portion of them—are brought into a condition favorable to nutritive assimilation. But this is not all. When the reaction,—after the cold pack—is normal, the column of blood which sets inward towards the chylopoietic organs very soon turns outward again, accelerating the entire circulation of these organs in the same direction. As a most important result, more nutriment is carried into the general circulation, and with the abatement of the gastric-intestinal hyperæmia, the appetite revives." Dr. Jacobi goes on to explain the effect of a prolonged wet pack in a manner at once so original and acute that I take the liberty of quoting from her book in extenso.

"Sleepiness during the pack," she says, "nearly always occurs in successful cases, and we have found the greatest amount of benefit to accrue when the patient was able to sleep for half an hour after the completion of the pack and massage. If during the first period of the pack we may assume, for reasons already stated, that blood circulates in increased volume and under increased pressure through the nerve centers, and that in consequence the acid fatigue products, which had been maintaining a permanent excitement of nerve elements, could be completely removed, the immediately subsequent

[1] Read before the New York Academy of Medicine, November 7, 1889.

diminution of blood supply, effected during the second part of the pack, cannot fail to be a great advantage. For it lowers the functional activity of the nerve tissues, that has been unduly prolonged, and brings them therefore into the condition which is a necessary preliminary to the beginning of nutritive assimilation. The diminution of the blood supply is not sufficient to interfere with this latter process, for it is not below the point which exists in sleep, the physiological period for nutritive assimilation in nervo-muscular tissues. Accepting Ranke's law for these tissues, "that they are only nourished when fatigued," *i. e.*, relaxed, we may see further—in the muscular relaxation induced by the warm moisture of the pack, a condition most favorable for the nutrition of muscles."

I feel a pride in laying before you these valuable deductions of our distinguished fellow, because Winternitz, who is most ingenious in explaining hydrotherapeutic procedures on a physiological basis, said in his great work: "The metabolic changes in heat abstraction and heat supply are in many directions still enveloped in a thick mantle of obscurity. It would be most desirable to fill up without delay these gaps in our science." This Dr. Putnam Jacobi has done to a great extent.

Investigation made upon the healthy and diseased subject enables us to ascertain the effects of *thermic influences upon the formation of carbonic acid* and the decomposition of albumen, which affords a clue to the changes impressed by them upon tissue metamorphosis. Liebermeister has proved beyond a doubt, that the excretion and production of carbonic acid are increased by cold bathing, the sitz bath, or even uncovering the body in cold air. In a bath of 64.4 the excretion of carbonic acid increases three-fold, and continues for some time. Roehrig and Znutz have shown by experiments on rabbits, that there is also a corresponding increase of the consumption of oxygen in the cold.

These investigations have been confirmed by Finkler on guinea pigs, Duke Carl Theodore on the cat, and by Carl Voit on man. Dujardin-Beaumetz quotes Quinquaud's well conceived and rigorously executed experiments, showing that more oxygen is taken up and CO_2 expelled under cold. He says that they decide the question from henceforth, and we are now warranted in affirming as a physical law, that under the influence of cold the regular consumption is energized and augmented; on condition always, that the refrigeration shall not exceed certain limits and cause depression of the rectal temperature below 30° C. (86° F.) (Leichtendeon-Balneathera.)

But if the cold baths are of long duration and abstract much heat from the interior, we have a diminution in the production of carbonic acid and of the consumption of oxygen.

Carl Voit has proved that to the effect of the cold bath upon certain peripheral nerves, is due the increased decomposition of non-nitrogenous matter in the animal economy. Pflueger, Roehrig, Znutz and Samuel agree with Voit's conclusions, that this increased change takes place in the muscles.

With regard to the decomposition of albumen, however, as demonstrated by the excretion of urea, Liebermeister affirms that it is not altered by the cold bath, unless the body temperature is greatly depressed. For Liebermeister has shown that the cold bath produces no change in the excretion of urea, unless it lowers the temperature considerably, when decomposition of albumen and fat takes place, as is shown by Carl Voit in the hibernating marmot. Senator's experiments on dogs also showed no change in urea excretion from low external temperature. The hot and vapor baths, on the contrary, which *increase* the temperature of the body, produce an increase of urea, as shown by Bartels, Paunyn and Schleich, and more recently by Godlewsky (Volk. Vort. 332, page 309).

The latter has shown conclusively a decided acceleration of oxidation of nitrogenized substances (nutrient and tissue albumen) which lasts several days beyond the bath, as well as an increased consumption of fat.

Thus we see that the prolonged wet pack of Putnam Jacobi approximates nearly the vapor bath of Bartels, Schleich and Godlewsky, and forms, as is well recognized in hydrotherapy, an intermediary method, capable of almost exact graduation. This is another illustration of the flexibility of hydriatic procedure, and the modifications we also may impress upon tissue metabolism by strictly following the guidance of physiological experiment.

SECRETION.—The effect of hydriatic procedures upon the secretions has been carefully studied in certain directions, since Winternitz said in 1880: "As far as I know, the influence of external thermal applications upon the secretion of urine has not been sufficiently investigated, especially as regards qualitative alteration which the urine undergoes in thermal operations; concerning the question we nowhere find precise answers."

In the same year one answer to the question was furnished in the little book of Dr. Mary Putnam Jacobi, on the "Wet Pack and Massage," which I have quoted already. Her observations made on healthy women, demonstrated that the wet pack is capable of increasing the water in the urine, and also the urea percentage, and in smaller proportions, its extractive and inorganic salts. During the hours following the pack, a movement of compensation occurred, in virtue of which the elimination of both the fluids and solids of the urine fell as much below the average, as it had risen before.

CLINICAL EVIDENCE. — Having in the imperfect manner, for which the time at my disposal is responsible, presented the historical and physiological grounds upon which I base my plea for the practical utilization of hydrotherapy, I proceed to discuss a few clinical points, which may succeed in winning you over to the acceptance of the views advocated.

Unfortunately *experience* has been so often invoked by the empirics upon the subject that the profession has looked askance upon this argument. I propose to limit the clinical demonstration to evidence derived from trustworthy sources, and from my own limited field of observation. I agree with the latest German authority on therapeutics, F. A. Hoffman, who says he does not deal with the disease, but with

the sick man, and who divides therapeutic methods into the direct, which acts by removing the cause, and the indirect, which, by influencing the circulation and nutrition of one or other organ, or the general tissue changes, seeks to remove disease or make it recede. But I would add a third method, viz.: that by which we may so impress the various functions of the body, chiefly through the innervation which governs them all, as to enhance the resisting power of the patient, and thus enable him to escape the dangers, which are known to be lethal. All these methods I propose to demonstrate, may be exemplified to a certain extent in the proper application of hydrotherapy. *Far be it from me*, however, to claim this as a universal remedy, which shall enable us to dispense with drugs. I stand second to no one in high appreciation of the medicinal agents, which the practice and custom of many years have established as reliable and especially of those more modern products of the pharmacist, whose effects have been demonstrated with so much precision. I claim for hydrotherapy only the position of a valuable but an indispensable auxiliary to other treatment.

As I define it, and as I would ask you to conceive it: *Hydrotherapy is the utilization of water at any temperature and in any form* (from ice to vapor), internally or externally, for the treatment of disease. I do not say the cure of disease. By this definition we emancipate it from hydropathy, or cold water cure, and place it clinically in the front rank of therapeutic measures.

We will now proceed to illustrate the three therapeutic methods I have mentioned by clinical evidence, and I propose in this paper to hold my personal experience, as far as possible, in the background, unless I can verify it by reports from other sources, in order to diminish the possible tendency to an over-zealous advocacy of hydrotherapy.

The removal of the cause of disease is not often within the province of physicians, since etiological factors are exceedingly difficult to discover. The modern discovery of the microbic origin of many diseases will, if verified by clinical experience, present a large field for therapeutic labor in this direction. Thus far less has been accomplished in this line than we wish and hope. In the gastric and intestinal diseases of infancy, however, we seem to be on the threshold of its fulfilment. Clinical study has demonstrated that many of these affections are due to the toxic products derived from the micro-organisms which have found their way into the alimentary canal, chiefly through milk food in the summer. To remove these, and to reinstate the gastro-intestinal function, water has been used with great success.

I will not here enter into details upon this subject, which I have fully discussed in the Pediatric Section of the Academy in a paper entitled "The Treatment of Summer Diarrhœa of Infants." I have there gone over the entire ground carefully, and I am glad to note that the same field has since that time been successively tilled by others.

Intestinal irrigation, carefully and thoroughly done with a large Nélaton catheter, with the patient on the abdomen, and by means of a fountain syringe holding not less than a quart of warm water, has proved the most efficient method of treating several types of summer diarrhœa, even after they had assumed a threatening phase. The literature of this subject is abundant. Dr. Seibert, of this city, has published important results from stomach irrigation alone, and Drs. Ebstein, Baginsky and others have established the purely hydriatic treatment as the most effective.

Another hydriatic method, which acts by removing the cause of disturbance, is the sipping of hot water an hour before meals, in dyspepsia. The hot water craze, which now has taken a firm hold upon the lay public, is but the legitimate outcome of a valuable therapeutic application of water, whose simplicity commends it at once to the judgment of the intelligent physician. Brought into prominence by Dr. Salisbury, who committed the error of most enthusiasts of regarding it as a panacea for most diseases, it has now been adopted by the profession as a most valuable agent in many gastric troubles. By removing the products of fermentation, by cleansing the mucous membrane of mucus, it restores tone and vigor to the gastric lining, and enables the natural forces to come into play. It is important to observe strict compliance with the rule laid down by the originator, viz: that the water should be sipped as hot as possible, and that an hour should elapse before a meal is taken. Examples of failures due to neglect of this rule are numerous in the experience of all medical men.

The second method of treatment referred to, viz., that which acts by affecting nutrition and tissue change, presents a broad field for the employment of hydrotherapy in its various modifications. To this category belong neurasthenia and other nervous diseases, rheumatism, gout, anæmia and chlorosis, obesity, scrofula, etc. For practical purposes in hydriatic management, I divide neurasthenia into two types: the erethic and the true asthenic. The former is characterized by an instability of the nerve forces, the latter by their enfeeblement. The former is most properly treated by soothing hydriatic measures, such as cool ablutions or prolonged wet packs, followed by the half-bath of 65° to 70° F. once or twice daily. The asthenic form, on the contrary, requires the stimulus from active reaction produced by the impingement of a mass of cold water for a brief period, and the effect is greatly enhanced by general faradization. Between these two extreme types there are intermediate forms, to which the flexible procedures of hydrotherapy adapt themselves admirably.

In no question of therapeutics is a judicious regard for the condition of the patient and the type of disease so important as in the selection of the proper method, temperature, length of time and frequency of repetition.

Mrs. D., aged thirty-three, came to me from Brooklyn; claims to be miserable, nervous and dyspeptic for years; has three children, youngest six years old, and was six months pregnant when she consulted me. I will not bore you with her catalogue of symptoms except to say that pulse was irregular, manner exceedingly agitated, eyes restive; she had no hope of recovery, having been under medical treatment constantly. Severe attacks of palpitation and fright

disturb her sleep. She claims to be unable to digest anything, because all food distends her stomach and produces violent eructations without relief. A full meal of mixed food (some of which she had not tasted for years) was ordered, and four hours later her stomach was washed out. Neither food nor mucus was found. Diagnosis: erethic type of gastric neurasthenia. Ordered aloes and mast. pill at bedtime; constant current (sixteen cells) to epigastrium by negative pole, positive in back; hot water an hour before breakfast; cold ablutions every morning while standing in fifteen inches of hot water, followed by friction. She was entirely restored in one month.

Miss W., daughter of an Ohio physician, aged twenty-three, anæmic, came to me May 15, 1889; ill three years. At first suffered fainting fits at menstrual period; afterwards violent pain in right hand, traversing body and concentrating in epigastrium, for which her father administered morphine for a month. Now her stomach became irritable, and has continued so until the present time. She vomited and spat up her food, more frequently solids. Sea baths did not improve her. She studied hard and got worse. Fall, 1888, lived on milk and farinaceous mush. She had now the stomach washed out regularly. She became emaciated; took peptonized milk for a month, vomited it; tried meat with same effect. Last fall lived on grapes, which agreed with her. Had tonics, pepsin, and all possible medication her father and brother could muster. She was sent to me by Dr. Bosworth after being in the city three weeks without improvement. Vomits every day. Diagnosis: gastric neurasthenia of the pure type. Stomach was washed once a week to remove fermenting material and mucus; general faradization daily; also the wet sheet. She received a brisk rubbing over the dripping sheet (water 60° F.) every morning.

MONTEFIORE HOME, NEW YORK.

Leo Ettinger, Resident Physician.

SUSPENSION TREATMENT OF POSTERIOR-SPINAL SCLEROSIS.

IN the early part of this year, when the reported success of Charcot with suspension in locomotor ataxia attracted attention, this method was introduced into the Home by the chief of staff, Dr. Baruch. As the home is intended solely for the treatment of incurable cases, the ataxic patients submitted to the suspension were in the last stages of the disease, and its value was submitted to the severest tests. Eight cases have been treated in the manner to be described. The apparatus used was that of Sayre; the neck and axillary bands were thoroughly padded with cotton batting. The patient was elevated to a height of two or three feet above the floor.

Suspension at beginning of treatment was for about thirty seconds, gradually increased.

The maximum period of suspension was seven minutes. The average was about three minutes.

The symptoms during suspension were slight, and in many cases there were none at all.

The symptoms in one case were very marked, vertigo, feeble heart, pallor, vomiting and faintness, compelling cessation of treatment.

The results of the treatment were marked in the majority of cases, as evidenced by relief of pains and incoördinate movements, disappearance of the sensation of constriction around the waist, and nutrition was improved. The following cases were systematically treated by suspension, and their prominent symptoms are briefly given with result of treatment:

CASE I.—Very marked case, incoördinate movements very severe, could not stand at all, severe pains and constriction around waist. Was suspended daily. Pains relieved, waist constriction totally gone, can stand for a few minutes to be dressed, incoördinate movements much less marked.

CASE II.—Very bad case, had no pain, but restless incoördinate movements, had a sense of restless nervousness. Movements have been less restless, and nervousness relieved by suspension.

CASE III.—Female, severe pains, could only walk when supported on both sides, incoördinate movements, paræsthesia, band constriction of waist.

Suspended an average of five minutes with relief; pain, paræsthesia, general nutrition improved. Can walk around ward by supporting herself against wall.

CASE IV.—Suspension cured bad symptoms noted above, treatment stopped.

CASE V.—Nutrition improved by suspension, but no other effects, bears it well.

CASE VI.—No ataxia, but very severe pains, materially relieved by suspension.

CASE VII.—Amaurosis marked symptom, no changes produced by suspension.

CASE VIII.—Same as case VII. —K. B. P.

MEDICO-CHIRURGICAL HOSPITAL.

MALARIAL CACHEXIA WITH FEVER.

MR. ——, age thirty-one, and a sailor by occupation, came into the hospital suffering with syphilitic rupia on the leg. This had nearly healed, but on October 16, 1889, in the middle of the day his temperature was found to be 102.5°; the same evening 103°; next morning 100.5°; evening 102.5°. This morning it is 101°. There is no intermission in the fever so far. An inflammation of the lungs or pleura might cause this, but it is not the cause here. On the other hand, among the continued fevers we have two that are prominent, typhoid and remittent. There are also simple continued fevers common in children, due to exertion, digestive disturbances. In diseases of zymotic character, the local lesions may be so slight as not to attract attention. Tonsillitis causes it. I do not find any evidence of organic inflammation or joint affection. It is not local or rheumatic. It may be malaria or typhoid then. The history is in favor of malaria, as fifteen years ago he had it severely, and has been subject to it at times since, and this is the time of the year that it usually asserts itself. I saw a case of obscure malaria at a health resort in the mountains. The boy took a fever that increased each day, and chills soon developed. There

was no malaria at his home, but I found that in going to the resort the train was delayed all night by the bank of a stream, and doubtless here is where the disease was contracted.

Now in addition to the fever in the patient before us there is marked jaundice. Conjunctiva is stained with bile, and the surface of the body is markedly discolored. About two years ago the jaundice first appeared. He gives the ordinary history of catarrh of the bile ducts. At present the stools show no deficiency of bile, but the urine is full of it, indicating an excess of it in the blood. I can not learn that it has been worse since he came into the hospital. The fever has nothing to do with the jaundice. There are several points that suggest typhoid—the dull look; the poor appetite; the coated tongue, and the tumid abdomen, which is not distinctly tympanitic, however. There are two fluid stools a day, that may be due to a dose of salts. There is no tenderness or gurgling. The spleen was enormously enlarged. There is no epistaxis, cough or delirium. I think then we may safely call this a malarial form of continued fever. He has been given quinine hydrochloras gr. xx every day since the onset, and as a result of this there is now a decided shrinkage of the spleen, and the fever is decreasing each day. Give in fever a light nutritive diet without meat. Bathe the skin each day. I might have given this man antipyrine, but I do not see any reason for deserting an old and tried remedy for a new and untried one. We know more about quinine and its action than of the newer remedies and I do not know of anything that will do as much good. This man's syphilitic history has no bearing on the present condition.—*Woodbury.*

PHILADELPHIA HOSPITAL.

CONGENITAL SYPHILIS.

THIS baby developed coryza, or snuffles, one week after birth, and after this there appeared an eruption and desquamation, which has a peculiar metallic appearance, and is confined to the upper extremities. The clinical history reveals congenital syphilis. Children suffering from this affection are usually born dead, or die in thirty-six hours after birth, from pneumonia or other lung trouble. The child may be born apparently healthy, but will develop the eruption in one to three weeks. After careful study, it is shown that the administration of calomel, gr. $\frac{1}{16}$–$\frac{1}{12}$, with a little soda twice a day, will do much more to remove the eruption than any other remedy you can employ. If this should irritate the stomach, use inunctions. Keep the child under constant treatment for three years, and alternate the mercury with iodide of potassium. Give a good diet, with careful treatment, and in the majority of cases you can free the child from the hereditary taint. Another point: a syphilitic baby can never infect its mother by nursing at the breast.—*Hirst.*

INFANTILE MAMMARY ABSCESS.

Here is a baby that presents an enlargement of the breast with a tendency to secrete milk. For a time we feared an abscess, but I think the danger is now past. About four days after birth appears an enlargement of the child's breasts, with a secretion of milk, irrespective of the sex. Occasionally this functional activity of the child's breasts becomes enormously increased, and in some cases mammary abscess results. In the first stage of the trouble use lead water and laudanum, as it is almost a specific, and in most cases it will abort an apparent abscess. If it continues to advance, use a poultice, open upon the first indication of pus, and treat accordingly.—*Hirst.*

PELVIC ABSCESS.

This woman the mother of several children, has been in ill health for some time, with a tendency to metrorrhagia and pain in the left iliac region. The pain is increased by motion, and relieved somewhat by lying on the back. These symptoms indicate some old pelvic inflammation which has left cicatricial bands or pockets of pus in the pelvic region. The uterus is normal in size and position, but behind it there is a fluctuating tumor the size of an egg which is sensitive. I also find surrounding œdema. This is a pelvic abscess. With such a history we must look for some specific cause. It may be of septic origin following labor; but in this case we obtain a clear history that before the birth of her last child she had a discharge from the vagina which was evidently gonorrhœal. In patients of her class the only cure is the removal of the diseased structures by laparotomy.

—*Hirst.*

DYSENTERY.

The patient, a Hungarian, walked here from the coal regions three months ago, and while on his way was taken ill with dysenteric symptoms, and passed frothy blood of a light scarlet hue. On admission he had pain in the back and lower part of the abdomen, with tenesmus. One week ago his right parotid gland became swollen, and was so much distended that he could scarcely open his mouth. This is the end of his course of dysentery. The parotitis is due to a change in the blood which occurs in typhus, typhoid, pneumonia, and other diseases of like character. It comes on when the patient is much run down. If it occurs in a man who is very weak from prolonged illness it is very serious, but in this case it is not. Before the swelling passes off there will be an abscess in this case; but there are many cases in which the swelling subsides in a couple of weeks. In an epidemic of cerebro-spinal meningitis some time ago, I had seven cases of parotitis, and in one the whole gland sloughed away. This patient has a slight elevation of temperature. In the first place he was given thymol, gr. v, every hour, with lead, opium, bismuth, pepsin and quinine. The gland was painted with iodine. In the treatment of dysentery you will find that that class do well under the saline treatment where there is a mild inflammation; but where the case is severe you must take a more defined course of treatment. Poultice the gland to bring the abscess to a head and then open it antiseptically.

—*Curtin.*

Two drops of creosote made from beech tar, given with a little water, is a specific for hiccough arising from drunkenness.—*Ind. Pharm.*

THE HEALTH OF PHILADELPHIA.

THE relative danger of death from the diseases most prevalent in Philadelphia may be judged from the following extracts, from the weekly report of interments:

Pulmonary consumption	53.
Inflammation of the lungs	33.
Heart disease	26.
Diphtheria	16.
Cancer	16.
Inflammation of the brain	14.
Croup	13.
Old age	13.
Convulsions	12.
Apoplexy	11.
Inanition	10.
Inflammation of kidneys	10.
Scarlatina	9.
Casualties	8.
Marasmus	8.
Typhoid fever	7.

Diphtheria and croup are on the increase, and the fact that they grow more prevalent at the same time is another proof of their common origin. The occurrence of sixteen deaths from cancer is probably due to the fact that at this season many such patients come to the city for treatment. In our news notes it will be seen that diphtheria continues to be reported in many places through the country. The continued rains have occasioned an unusual prevalence of catarrhal affections, which do not appear upon the mortality tables. It would be gratifying to those interested in medical climatology, were physicians to report all the cases they were called upon to attend, whether fatal or not.

Public attention is still occupied with the prevalence of typhoid fever, to an extent out of all proportion to the importance of the disease at present. If the attention given to the subject of the transmission of typhoid fever by drinking water were transferred to that of the transmission of tuberculosis by food products, much good would result.

We have already shown that the small number of typhoid cases is inconsistent with the theory of infection through the water-supply; and the continued decrease shows that this conclusion is correct, as the water-supply is unchanged. It is probable that the improvement is due to the attention of physicians generally being directed to the management of individual cases. It is in the power of every physician who attends a case of typhoid fever to absolutely prevent it from becoming a source of further infection, and this is an individual responsibility which cannot be shifted to the shoulders of the municipality; not even if the physician is not a "believer in bugs." The world still waits for the final extinction of smallpox, until the last man shall have been convinced of the efficacy of vaccination. With typhoid, there is less excuse for unbelievers, as the measures required to prevent infection are not in any way harmful to the patient. An ideal hygiene of the patient, his sickroom and attendants, with the destruction by fire of all excreta and contaminated articles, is not difficult, unduly expensive, or in way objectionable; and whether the physician in attendance believes in the infection or not, the evidence is strong enough to warrant him in keeping on the safe side by employing the proper precautions.

This individual duty the TIMES AND REGISTER has persistently held up to the physicians of Philadelphia, and we fully believe that to the recognition of this obligation is due the gratifying decline in the number of typhoid cases. Not that the danger has been at any time very great, for a study of the records of the Health Office shows conclusively that the ratio of deaths to the population in this city is declining as the city grows larger. In fact, there are sufficient grounds for the belief that the persistent agitation of this subject is not solely due to solicitude for the public welfare; and that the efforts of certain persons to discredit the Schuylkill water and impose upon it a condemnation, which is at variance with the evidence in the case, are probably due to their willingness to become the builders of a mighty aqueduct, reaching from the Delaware above Trenton to this city. The fact that the water of the Delaware above Trenton contains more organic matter than that of the Schuylkill at Philadelphia is studiously ignored; this being a most effectual method in dealing with awkward facts. And yet before spending the huge sum of thirty or more millions of dollars, these lovers of the public weal might well bestow a little consideration upon such an important matter. We are not prepared to say that thirty millions is too large a sum to be expended in securing a supply of pure water for this great city; but it is assuredly too much to invest in that which is worse than what we have now. The great increase in taxation thus necessitated, an increase which would be felt by every one, rich and poor alike, who would be required to pay higher taxes or rents, would be but poorly compensated by the increase of wisdom coming from such

dearly-purchased experience. It is a matter of satisfaction to note that the we have in Mayor Fitler an executive, and in the *Public Ledger* a representative journal, which refuse to be led away by popular clamor, and persist in guarding the public interests. Too frequently it occurs that the direct monetary interests of the few have advocates in plenty, while those of the vast majority, whose interest is but small or indirect in the case of each individual, though infinitely greater in the whole, fail for lack of representation. The difference in the men who take the one side or the other is simply that between the politician and the statesman.

With much regret we note that several Philadelphia physicians, whose professional and moral standing lifts them above the suspicion of interested motives, should have chosen this inauspicious time to make public a manifesto directed against our water supply. After keeping silent while typhoid fever was prevalent, why advert to it now, when the disease is declining? The terms in which their communication were couched, were so extravagant as to bring ridicule upon the profession of which these gentlemen are distinguished members, in the eyes of all persons who are conversant with the facts of the case. If one may read between the lines, this communication was gotten up by some person who is interested in the aqueduct scheme, or who desires to make political capital out of the Mayor's opposition thereto; and the signatures of these eminent men were adroitly secured by appealing to their interest in the public health. It could not have resulted from a mature study of the case—its causes, etc.—for such a diagnosis could not have led to the letter to the Board of Health. As the signers are among the busiest of our city doctors, it seems unlikely that any one of them took the time to study the subject before affixing their names to that singular document—which the impartial critic must pronounce ill-timed, unnecessary, and calculated to do much harm to the business interests of the city—by creating the impression that the disease in question is much more prevalent than is really the case.

JOURNALISTIC VERACITY.

AN honest writer in one of the foreign journals begins his article with these words: "It is with the most profound consternation that I have to report these five cases of death, due, without any doubt, to the treatment employed by me." We congratulate the journal in which this article appears for having the support of so straightforward a contributor, and we congratulate the latter upon the possession of so true a spirit for scientific inquiry and investigation. It is unfortunate that five deaths should have occurred, even though science may have been advanced a degree by the same; but it is a noble disposition in a man who, having been unfortunate in losing his own cases, is independent enough to hold forth his own mistakes as a lesson to his professional brethren. Such a mind is of the true scientific cast, and its possessor is bound to adorn his profession if he be industrious and is wise enough to learn of his own errors as well as indicate them to others.

One of our contemporaries comments upon this honest admission by saying that "not many would have the courage to do so in such a blunt fashion." Just here is one of the darkest spots on medical literature as a representation of scientific thought and inquiry. Our medical journals are filled with articles and notes reporting wonderful cures and unvarying successes. Scarcely a new drug is thrown upon the market before the columns of the periodicals are filled with the marvellous results of its administration. At rare intervals someone will be courageous enough to relate a misfortune arising from its use; but it is amusing to note how such misfortunes are always patched up with explanations and extenuations to relieve the doctor of all blame. The organ of a school, clique, or single individual rarely contains anything of a detrimental character concerning those whom it represents. This, of course, deprives the said journal of all value, and lies pretty close upon the borderland of quackery. At all events, it is not as it should be when the journal is posing as the unbiased organ of science. We have knowledge of papers being declined by certain journals, though containing matter of the highest scientific merit, simply because the authors were not of the same "set" as the editor and his friends; and we have seen articles not worth the ink they were printed with inserted in those same journals, simply because they advertised some one or more members of the "set." Favoritism is an outrage upon science, and every man who is interested in the good of his profession at large should exert all his influence to crush it out of existence and protect his calling from such a stigma.

So long ago as the sixteenth century Bouchet lamentably asked: "Is it not strange that doctors lie so often, and that it is allowable for the profession to lie?" In no occupation in life is secrecy granted to so great an extent as in that of medicine; and yet in none, perhaps by reason of the great issues involved, ought it to be less so. The preacher, the lawyer, the actor, the mechanic must always display their work before the public, or at least their confréres; but a physician may sit and watch in secret over a dying patient, and when he emerges from the sick room none can tell whether his treatment were not the result of the grossest ignorance. A certificate of death is given to the family, and the doctor goes to his society to report or not, as he pleases, the case patched up and explained according as his own sweet will dictates. Let anyone compare the statements which he hears, when in conversation with general practitioners, in regard to the results of their treatment, and see if they harmonize with the almost

universal good fortune which one reads of in the society reports and columns of the journals.

Are we too cynical, and too harsh upon our own beloved profession? We hope not, for we are speaking in all sincerity and with a desire to see medicine advanced to a still higher degree of success. We desire to see medical journalism the true exponent of scientific thought and investigation, which it can only become by the strictest adherence to unbiased truth, by the report of failures as well as of successes. Often we learn more from the former than the latter, and a contributor who selfishly withholds his errors merely to enhance his own credit, is not a true lover of his art and science; nay, more, he is robbing his fellow-practitioners—and mankind at large—of that knowledge which would prevent them from falling into the same errors. Let us not be slow in honoring scientific integrity, independence, and love of truth for its own sake, and there is no question but that, in a short time, all the isms of quackery will be made to disappear, and true medicine will achieve even grander results than it has in the past.

THE CODE OF ETHICS IN GERMANY.

OUR Teutonic confrères have long maintained—and with justice, too—that they do not require a code for their guidance, because the ranks of the profession are recruited from educated men, whose chief aim in life is scientific advancement. It seems, however, that the strife for pelf has invaded those ranks, and that now it becomes necessary to formulate rules for the government of medical bodies. We find an excellent reproduction of the American Code of Ethics in the District Association of the City of Dresden.

How familiar the following headings read:

I. Duties of physicians towards each other, and towards the profession in general.

II. Of consultations.

III. Duties towards patients of another physician.

The following, however, is an innovation of the American Code:

IV. Committee of Honor.

§ 19.—For the decision of disputes between members, and for the maintenance of the rules, a Court of Honor is instituted. This Committee consists of seven members. 1. The President or Vice-President. 2. Four members, chosen annually for the purpose, with substitutes. 3. Two confidential friends, selected respectively by the disputants. The rules of the Committee are admirably adapted for the settlement of all disputes between members, with the right of appeal from the decision to the Minister of the Interior, after the Society has voted upon the report of the Committee of Honor.

We regard such a committee as a valuable innovation, which would certainly tend to diminish public discussions of grievances, and thus prevent the lowering of respect for our calling, which such disputes invariably bring in their train. A recent glaring illustration was furnished by the scandalous acrimonious newspaper contention between two eminent members of our profession, which was witnessed with pain and humiliation by every physician who has the good name of his profession at heart.

Annotations.

WOMEN IN MEN'S DRESS.

"WHETHER[1] as the world grows wiser, women will eventually adopt men's dress, or wear it and womanly attire interchangeably, according to the occasion, is a question. Those who are ready to cry 'Impossible,' should study the masculine dress of men only a century ago. After centuries of brilliant dressing among those whose income allowed of it, the sterner sex has turned to attire of simple cut and sober colors. That there is a tendency among women to assume male attire, as more convenient or as a disguise, the many newspaper accounts of women discovered in coat and trousers, which in some instances they had worn for years without betraying their sex, sufficiently evinces.

"Several distinguished women have dressed as men. Rosa Bonheur, the painter, works in full male attire and resumes her petticoats in the evening. Louisa Lawson, the sculptress, finds it convenient to wear trousers and coat when at work. Sara Bernhardt, in her studio, assumes a black velvet suit of clothes, in which she is conscious that she looks very charming. Mme. Dieulafoy, the French explorer and scientist, who has done so much to increase our knowledge of Persian archæology, also looks much more coquettish and winsome in the costume she adopted while journeying in strange lands, than in the skirts which she wears in Paris. Indeed, even in Paris, her only return to feminine costume is in the substitution of skirts for trousers. The coat and vest, the shirt, collars, and cuffs are retained. When travelling she disguises herself in a loose and long paletot. But one sees the woman in the feet and ankles, the hands and wrists, the pretty throat, and the small ears. Her light brown hair is cut close."

Now that woman has entered the labor field to battle in the struggle for daily bread, the question of the most suitable dress for her working hours deserves some attention. We call ourselves a practical nation, and affirm that this age is distinguished above all that have preceded it for its materialistic, utilitarian tendencies. Yet every accident in which a woman's long skirts cause her to be whirled into death by catching in the machinery, is an evidence that if our claims be true, we have advanced but a lamentably short distance in the study of the fitness of things. The long skirt is of the drawing-room, where woman is a thing of grace and beauty; where she receives the respectful homage of the coarser sex. But in the factory, she is but a worker, like the man; and her dress should assuredly be that which is best

[1] New York *Evening Telegram.*

suited to her occupation. In the streets, too, there are many occasions when convenience, health, and security would be enhanced by the adoption of male attire. The failure of the "Bloomer" movement was due to the mistaken idea of its originators, who endeavored to render the costume popular, or fashionable, by putting it upon the market when there was no necessity for it. Should such a movement be started now, beginning where the need is most obvious, in the factories, it might have a better chance of success.

AINHUM, A BRAZILIAN DISEASE.

AINHUM was first systematically described by a Brazilian surgeon as attacking colored races in Brazil. The merit of its actual discovery, as Dr. Radcliffe Crocker and others have pointed out, is due to Dr. Clarke, who described the disease before the Epidemiological Society in 1860, as a dry gangrene of the little toe among the natives of the Gold Coast. Dr. Da Silva, Lima, however, described ainhum as a disorder long known as existing among Africans and Creoles in South America, first writing about it in the *Gazeta Medica de Bahia* in 1867. Ainhum consists in hypertrophy and degenerative changes in the little toe, a constriction forming and slowly becoming deeper until the digit is amputated, spontaneously or otherwise. The disease is often symmetrical, and may last for years. It is now known that the fourth, or even the great toe, may be affected, and Egles describes a case where a finger was attacked. It is frequent near Bahia, and also occurs in the Southern States of America, the West Indies, the West Coast of Africa, India (where Hindoos are also liable to the disease), Réunion, and Nossi-bé. M. Cogues has described a case of ainhum, which occurred in Madagascar, in the March number of the *Archives de Médecine Navale*. The pathology of ainhum is obscure, and although spontaneous amputation of digits is a feature in some forms of leprosy, it is by no means certain that the two diseases are closely allied.

British Medical Journal.

Letters to the Editor.

RUPTURE OF THE UTERUS DURING LABOR.

ON Friday morning, November 22, 1889, I was called, about 9 A. M., to see Mrs. B. G., in labor with her seventh child. Oldest child was eleven, youngest two years. Mrs. G.'s weight was nearly three hundred pounds. I attended her in previous confinements; the labors were always natural and not very tedious.

On first examination, about 9.30 A. M., I found the os slightly dilated and pains not severe. About 12 M. the patient went to bed, the pains having become more severe and the os well dilated, with the vertex presenting to the left. About 12.30 the membranes ruptured, the head engaged in the superior strait. At 2.45 rotation had taken place, the head entering the inferior strait.

At this time, as the pains were growing weaker, I gave her one teaspoonful fl. ex. ergot, which had no effect on the pains. In about fifteen minutes Mrs. G. turned from the right to the left side, and immediately back again, when she complained of violent pains in the epigastric region, and stated that all the labor pains had ceased. On making an examination I found that the head had receded, could not be felt at all, and that there was considerable hemorrhage. At once I concluded there was a rupture of the uterus. I sent for Dr. Jos. Thomas, in consultation. On his arrival, we decided to turn and deliver, if possible. On introducing my hand I grasped a foot without any difficulty, and delivered the mother of a child and placenta. I felt convinced that the child must have been in the abdominal cavity, as there was no resistance in turning from contraction of the uterus. It was a very large child, weighing about twelve pounds. There was scarcely any hemorrhage after the delivery. As Mrs. G. was still complaining of severe pain in the epigastrium, I gave her one-half grain morphine, which was repeated about midnight, when the pain ceased, and she rested comfortably until morning, when I relieved the bladder by catheter, and gave a vaginal injection of sulphocarbolate of zinc. The pain came on again and I gave her morphine, which was then repeated at intervals until the end.

During all this time the pulse was good. Saturday night I used the catheter again, after which she passed urine voluntarily. Sunday morning she had some fever and thirst; the temperature was 101; the pulse quick; the breathing labored. From this time on she grew gradually weaker, and the pain continued until death came to her relief, on Monday at 6 P. M.

There are several remarkable features in connection with this case beside its rare occurrence. There was no vomiting, nor any sudden shock or sign of collapse; the hemorrhage was slight; neither did the patient have the slightest indication of chill at any time. After death there was an enormous discharge of blood from the vagina. On Tuesday afternoon Dr. Thomas and I made an examination, and found every evidence of peritoneal inflammation. The abdomen contained much coagulated blood and serum. The uterus and vagina were found to be lacerated in the posterior median portion to the extent of about six inches. The uterus was healthy, as well as the walls of the vagina. As to the cause of the accident, I feel confident that it was the turning in bed, in conjunction with her great weight and the large size of the child. As the ergot did not increase the severity of the pains, I feel satisfied that it could not have had anything to do with the accident.

W. H. MEREDITH.

QUAKERTOWN, PA.

HEROIC treatment of retention of a decomposing placenta after a four months' abortion, is reported by Roosenburg, who extirpated the uterus per vaginam, after failure to remove the stinking mass.

Society Notes.

THE SOUTHERN SURGICAL AND GYNÆCOLOGICAL ASSOCIATION.

Second Annual Meeting held in Nashville, Tennessee, November 12, 13, and 14, 1889.

NOVEMBER 12.—FIRST DAY.—MORNING SESSION.

[Concluded from page 762]

DR. B. E. HADRA, of Galveston, Tennessee, read a paper entitled

THE OPEN ABDOMINAL TREATMENT,

in which he said that abdominal surgery, notwithstanding its immense progress, has not as yet given even a moderate degree of satisfaction in acute, diffuse, septic peritonitis. Chronic infectious processes offer much better prospects for surgical interference, such as tuberculosis, actinomycosis, and the recently described microbic peritonitis of as yet unknown origin.

The points making the diffuse septic peritonitis are:

1. The extensive area of peritoneal surface, with its enormous power of resorption of the poisonous fluid.

2. The active secretion into the sac, thereby furnishing cultivating fluids for the germs.

3. The ready absorption by the lymphatics of the diaphragm.

4. General distribution of the poison by intestinal peristalsis.

5. The infection of the intestinal walls from without, and the additional infection of the peritoneal cavity by transudation and immigration of germs from the inside of the bowels.

6. Distention of the bowels increasing the pressure and resorption.

7. The impeding effect of this latter condition upon respiration, defecation and secretion of urine, leading to systemic poisoning by retained products of oxidization.

8. In perforative cases the contamination by fæcal matter; in stab and gunshot wounds by other impurities, bile, urine, etc., and, above all, contaminated blood.

The indications for treatment—besides supporting the patient's strength, relieving suffering, giving proper action to the bowels, kidneys (in short, besides the general medical treatment, are:

1. To remove the obnoxious material—germs, fæcal matter and urine.

2 To prevent its new formation or a repetition of its entrance. The sac should be kept dry, to deprive the germ of its soil. The breaks have to be mended so that the channels of contamination may not lead to the outside.

3. To prevent the bowels from distributing the poison throughout the whole cavity.

4. To counteract pressure and suction, in order to prevent resorption of the poison.

5. To prevent infection of the peritoneum and the bowel.

6. To relieve pressure in order to avoid disintegration and paralysis of the different structures.

7. To free respiration, defecation, and urination, with tympanites, as developed.

DR. L. S. MCMURTRY, of Danville, Kentucky, read a paper on

TWENTY CONSECUTIVE CASES OF ABDOMINAL SECTION.

The series of cases comprised the first twenty abdominal sections performed by him, and illustrated a variety of pathological conditions and diverse complications. All these cases were in private practice, and, with two exceptions, all the operations were done at the homes of the patients. Two cases were treated as private patients in a well appointed hospital. In many cases operative treatment was only accepted after all ordinary and so-called conservative measures had been exhausted; and in several cases the operation was only accepted when the patient's condition was regarded as hopeless by physician and family. In no case, however, desperate or complicated, was an operation refused.

Dr. McMurtry said thorough work, irrigation, and drainage, all conjoined, give the only basis of success in the cases reported. In a number of his cases he had operated in the midst of active peritonitis, with vomiting and tympanites. In this condition of affairs he had witnessed the most gratifying results from persistent and oft-repeated exhibition of calomel, dropping two or three grains on the tongue every hour until the bowels were freely moved. Increasing experience has impressed him more and more with the difficulties of abdominal work, and makes him less confident of meeting often with simple cases.

He closed his paper with a plea for earlier interference in abdominal diseases. When operations are done in good time, before emaciation and exhaustion come, and before repeated attacks of peritonitis have complicated the comparatively easy task for the surgeon, then will the surgeon's results excel even the brilliant records of the present time.

DR. RICHARD DOUGLAS, of Nashville, read a paper entitled

COMPLICATIONS OCCURRING IN THE CLINICAL HISTORY OF OVARIAN TUMORS.

The papers of Drs. Hadra, McMurtry, and Douglas were discussed at length by Drs. Potter, Roberts, Stone, Wathen, Engelmann, Hardon, Haggard, Lydston, Cunningham, Brownrigg, W. E. B. Davis, and discussion closed by the essayists.

EVENING SESSION.

DR. G. FRANK LYDSTON, of Chicago, Illinois, read a paper on

TROPHO-NEUROSIS AS A FACTOR IN THE PHENOMENA OF SYPHILIS,

in which he called attention to the relation of disturbances of the trophic function of the sympathetic nervous system, which the author claimed were the essence of all the phenomena of syphilis. He said: "The relations of certain syphilitic phenomena to organic or functional disturbances of the nervous system, and particularly the sympathetic system, are

manifested here and there along the whole line of morbid phenomena developed in the course of the disease. Syphilitic fever is undoubtedly dependent upon the action of a special poison upon the sympathetic nervous system. From what we know of the trophic functions of the sympathetic, we are justified in inferring that the majority of fevers are dependent upon the action of a specific poison upon the sypathetic ganglia. The syphilitic poison may produce disturbances of the sympathetic with perversion of tissue metabolism and excessive production of heat. The inconstancy of the syphilitic fever is explicable upon the ground of idiosyncrasy. The syphilitic roseola has been demonstrated to be an exception to the rule that syphilitic lesions are due to a collection of proliferating cells. It is due to vaso-motor disturbance, with resulting dilatation of capillaries. This nervous disturbance is dependent upon the impression of the syphilis poison upon the sympathetic ganglia. The accumulation of cells in the more pronounced lesions of syphilis is simply an exaggeration of the normal process of tissue building. As is well known such tissue building is presided over by the filaments of the sympathetic nerves."

The symmetry of the peripheral phenomena of syphilis is suggestive of some causal condition affecting the central nervous system. As an illustration of the manner in which a nerve lesion could produce disturbed nutrition the author mentioned herpes zoster. Some of the lesions of syphilis which are difficult of explanation upon mechanical grounds, *i. e.*, upon the theory of localized cell accumulation, are readily explicable by central or local nervous disturbance. For example, the alopecia of syphilis is similar to that which occurs in other diseases, as a consequence of local and general malnutrition, incidental to disturbed nervous supply—as, for instances, alopecia areata, the alopecia produced by fevers, and the alopecia produced by neuralgic affections of the head. That the nutrition of the hair is profoundly affected by nervous disturbances is shown by the result of fright in producing blanching of the hair.

One of the principal arguments in favor of the theory that tropho-neurosis is the foundation of syphilitic processes, is the peculiar action of the disease when it attacks certain parts, syphilis seemingly possessing the power of dissecting out definite portions of osseous tissue (apparently by cutting off their nutritive supply) in a manner as cleanly as it can be done by the knife. Thus the speaker has in his possession specimens of the intermaxillary bone, portions of the alveolar process of the maxilla, the palatal and nasal processes of the superior maxilla, the malar and ossa nasi, which became necrosed and were removed from cases of late syphilis. These fragments present as natural a conformation as in their healthy condition. The ordinary explanation of destruction by pressure of syphilitic exudate will not suffice in these cases. If they be observed carefully it will be found that the first symptoms experienced by the patient are like those due to the presence of a foreign body, *i. e.*, dead bone in the tissues. If pressure were the cause of the necrosis the death of the bone would be preceded by more or less painful swelling and inflammation.

He claimed that all of the pathological processes incidental to syphilis are due to disturbances of nutrition produced by the impression of the syphilitic poison upon the sympathetic nervous system, and that it is immaterial to the cogency of this theory whether the poison of syphilis be a microbe, bacillus, degraded cell or chemical poison. If any attempt has been made to show that tropho-neurosis is the basis of all syphilitic phenomena, the author is not aware of it.

Third day—Morning Session.

Dr. John Brownrigg, of Columbus, Miss., read a paper on

Gunshot fractures of the femur,

in which he discussed the class of cases requiring amputation, and those in which a more conservative course should be pursued. He exhibited several appliances devised by himself.

Dr. Hunter McGuire, of Richmond, Va., read a paper on the

Treatment of cystitis in women,

which was followed by a paper on the

Treatment of contracted bladder by hot water dilatation,

by Dr. I. S. Stone, of Lincoln, Va.

During the past few years certain protracted cases of cystitis, occurring chiefly in women, have been observed by Dr. Stone, which have resisted all known forms of medical treatment and necessitated some surgical or mechanical measure of relief.

He describes the manner of dilatation as follows: "The patient is given morphine sulphate, gr. ¼, atropine sul., gr. $\frac{1}{100}$ hypodermically. She is placed on her back on a table for convenience, although it would answer to arrange the bed with the patient thereon to suit the operator. A soft catheter is at once inserted into the bladder, and, after the urine has escaped, hot water (temperature 110°) is thrown into the bladder until the patient will no longer bear it. This is allowed to escape and is measured, giving the full size of the bladder in its present condition. As the morphine gradually becomes absorbed, the patient will bear still further distention, each time perhaps one drachm may be added to the capacity of the bladder. I prefer using a rubber-ball syringe holding two to four ounces. The pressure of the hand is safer than that of the tube or funnel, or any instrumental gauge, as the patient generally is unable to resist the tendency to strain, owing to tenesmus produced by the expansion. As each *séance* should continue thirty to sixty minutes, the bladder may be filled and emptied many times, and at first the operator must be well satisfied if the gain is only one or two drachms in a bladder whose capacity is perhaps only two ounces. As the patient becomes fully under the influence of the morphine, the water may be increased in temperature to 120° or 125° F. The very best effect follows its use when it is at this temperature."

These papers were discussed by Drs. Lydston, Davis, Engelman, Roberts, Brokaw, Hadra, and closed by essayists.

Dr. Bedford Brown, of Alexandria, Va., read a paper entitled

REMARKS ON CERTAIN OBSCURE AND MINOR FORMS OF PELVIC CELLULITIS SIMULATING MALARIAL FEVER.

By referring to his note-book he found some twelve cases of pelvic cellulitis, some of a grave and others of a minor form, but all so very obscure in their manifestation of the presence of local lesion as to be well calculated to mislead and to cause a mistaken or false diagnosis to be made of malarial fever. There was nothing in these cases to call the attention to the pelvic organs. He has, in a number of instances, seen those cases run their course from beginning to end without manifesting the first symptoms of local disease in the pelvis, so that the resemblance to malarial fever was very nearly complete.

Dr. Joseph Taber Johnson, of Washington, D. C., presented a paper entitled,

OBSERVATIONS BASED UPON AN EXPERIENCE OF SEVENTY-TWO MISCELLANEOUS ABDOMINAL SECTIONS.

Of this number, 29 were for the removal of ovarian tumors, varying in size from one to sixty-four pounds; 26 recoveries, and 3 deaths; 29 cases of removal of the uterine appendages, with 27 recoveries and 2 deaths; 7 supra-vaginal hysterectomies for large uterine fibroids, with 3 recoveries and 4 deaths; 1 Cæsarean section, death on the tenth day; 1 cyst of the kidney, weighing seventy-four pounds, died of exhaustion; 1 fatal case of extra-uterine pregnancy, operated on six weeks after rupture, general peritonitis, with pulse 150, temperature 103, for the week previous; 1 fatal case of general abdominal cancer, 3 exploratory incisions, all recovered. Total, 72 laparotomies, with 59 recoveries and 13 deaths.

Of the 58 ovarian operations, the first 3 deaths were the second and third and fifth of his series. In the last 52 ovarian operations there have been only 2 deaths—one of these was from tetanus, occurring on the fifteenth day after operation, when everything indicated a perfect recovery. The other was an insane patient, who had been four years in an insane asylum on account of nymphomania. She could not be entirely controlled, and her efforts to get out of bed set up inflammation about the abdominal sutures, causing an abscess, which burst internally and caused death.

Dr. Johnson emphasized the statement that experience in operating was nowhere so valuable as in the abdominal cavity; that the "unexpected" was so often found, that many cases would be lost if the operator was not prepared for, and equal to, the emergencies as they "unexpectedly" arose.

The following papers were read by title:

1. Puerperal Eclampsia, by John Herbert Claiborne, Petersburg, Va.

2. Laparotomy in Intestinal Obstruction, by Cornelius Kollock, A.M., M.D., Cheraw, S. C.

3. The Causes of Frequent Failure of Relief of Reflex Symptoms After Trachelorrhaphy, by W. F. Hyer, M.D., Meridian, Miss.

The following officers were elected: President, Dr. Geo. J. Engelmann, of St. Louis, Mo.; First Vice-President, Dr. B. E. Hadra, of Galveston, Tenn.; Second Vice President, Dr. Duncan Eve, of Nashville, Tenn.; Secretary, Dr. W. E. B. Davis, of Birmingham, Ala.; Treasurer, Dr. Hardin P. Cochrane, of Birmingham, Ala.

On motion, the Association adjourned to meet in Atlanta, Ga., second Tuesday in November, 1890.

AMERICAN PUBLIC HEALTH ASSOCIATION.

Dr. BENJAMIN LEE, Secretary of the State Board of Health, drew the following conclusions at the end of a recent paper, read by himself, upon the question,

DO THE SANITARY INTERESTS OF THE UNITED STATES DEMAND THE ANNEXATION OF CUBA?

1. The exigencies of traffic and travel render rapid and constant communication between the United States and Havana a necessity.

2. Havana is one of the most notorious breeding places of yellow fever, and is never free from its presence.

3. The only means by which the germs of this disease can be eradicated are a proper system of sewerage and drainage, which shall deliver the filth of the city at a distant point into the waters of the ocean, and the removal of all the feculent soil.

4. There is no hope that the Spanish Government will ever undertake a work of this magnitude for a dependency.

5. The introduction of yellow fever into the United States through both legitimate and illegal channels of trade must be of frequent occurrence, so long as this condition of things continues.

6. A single wide-spread epidemic of yellow fever would cost the United States more in money—to say nothing of the grief and misery it would entail—than the purchase money of Cuba.

7. The precautions against the spread of small pox in Cuba are entirely inadequate, and are rendered ineffective by reason of the superstition of a large proportion of the inhabitants. Hence, epidemics of that loathsome disease are of frequent occurrence.

8. Leprosy prevails in Havana and the Island of Cuba to a serious and constantly increasing extent.

9. Leprosy is absolutely unrestricted in this island. While there is an immense and admirably-administered Leper Hospital in Havana, its inmates go and come among the residents of the city and country at will, until locomotion is rendered impossible by mutilation.

10. The ravages of the disease are confined to no class or race.

11. Leprosy has already obtained a foothold in the United States, in the ports nearest to, and in most constant communication with, the Island of Cuba.

12. Leprosy has but one history—that of constant progression—unless it is checked by isolation of the most absolute and unrelenting character.

13 No center of leprosy has ever originated in the United States. The importation of the first case of a series can always be distinctly traced.

In view of the truth of the above theses, I feel myself warranted in proposing the following resolutions for the consideration of the A. P. H. Association :

Resolved, That in view of the constant menace to the health of the United States from the unintermitted presence of the three most serious known contagions in the Island of Cuba, a condition which must continue so long as this island is a mere dependence of a country three thousand miles distant, this Association respectfully urges upon his Excellency, the President of the United States, the expediency of opening negotiations with the Spanish Government, with a view to an amicable transfer of the said island to the Government of the United States.

Resolved, That in the meantime, this Association, recognizing the admirable precautions taken by the United States Marine Hospital Service, and by the State Board of Health of Florida, to prevent the introduction of yellow fever into this country, respectfully request Supervising Surgeon General Hamilton, of the United States Marine Hospital Service, the Honorable the State Board of Health of Florida, and all Quarantine Commissioners of ports having intercourse with Cuban ports, to exercise the same vigilance with regard to leprôsy that is already observed in the case of yellow fever during what is known as Quarantine Season.

Resolved, That the Secretary be instructed to transmit copies of the above resolutions to the several officials therein indicated.

The second resolution was passed, and the said officials notified of its contents.

1532 PINE ST., PHILA.

ST. CHARLES COUNTY (MISSOURI) MEDICAL ASSOCIATION.

THE St. Charles County Medical Association held its quarterly convention Tuesday, November 19, at Warrenton, in the hall of the Germania Literary Society. After the usual preliminaries, Dr. Koch, President of the Central Wesleyan College, was introduced, and called upon to address the Convention. He responded with a few appropriate remarks, extending a hearty welcome to the Association. Dr. Middlekamp, after a few words of wel come, dwelt to some extent on the wonderful advances made in medicine and surgery. Dr. Vinke, in behalf of the Association, expressed thanks for the kind reception, and in the course of his remarks became quite complimentary to Dr. Middlekamp. Several physicians of this and adjoining counties were, on motion, elected honorary members of the Association.

In the afternoon session DR. MIDDLEKAMP read a paper on the

IDEAL SURGEON.

The subject was so thoroughly treated that, it seemed, no one had the heart to open a general discussion. Several interesting cases were reported, after which DR. BOLTEZER read a paper on

ERGOT IN PARTURITION.

A general and lively discussion took place, during which many and various views were expressed on the subject.

It being impossible to induce the Association to stay for an evening session, it was decided to have the next convention to take place at St. Charles, Mo. House adjourned.

On invitation from Prof. Frick, the Association amused themselves by examining specimens in the college museum until train time.

J. H. Stumburg, St. Charles ; T. J. Evans, Wentzville ; J. D. Evans, High Hill ; C. M. Johnson, St. Charles ; S. J. Burch, Rhineland, were appointed to read essays at the next meeting.

Book Reviews.

A TEXT-BOOK OF PRACTICAL MEDICINE. By ALFRED L. LOOMIS, M.D., LL.D. Eighth Edition. New York : Wm. Wood & Co., Publishers. With 215 Illustrations ; pp. 1149.

"The work has been thoroughly revised and largely rewritten. About fifty pages have been added. Many important changes and additions will be noticed. Among these are brief descriptions of the more frequent pathological processes and a detailed statement of the methods employed in bacteriological study, with an enumeration of the distinguishing characteristics of those micro-organisms which at the present time are regarded as pathogenic. Several additions have been made to the list of diseases considered. A lithographic plate has been introduced into the portion treating of bacteriology, which subject has been carefully discussed and brought up to the present date."

It is to be regretted that the results of bacteriological study do not appear also in the parts relating to treatment. In somer espects the book resembles Flint's work, in the poverty of the therapeusis, as well as in the excellent description of the symptoms. In pneumonia, for instance, the author has found nothing better than opium ; in acute tuberculosis he has nothing else to suggest.

Pamphlets.

Cases of Ocular Paralysis, by Alvin A. Hubbell, M.D., Professor of Diseases of the Eye, Ear and Throat in the Medical Department of Niagara University, Buffalo, N. Y. Reprint from *Buffalo Medical and Surgical Journal*, September, 1889.

Pennsylvania State College Agricultural Experiment Station. *Bulletin*, No. 8, July, 1889.

Proceedings and Addresses at a Sanitary Convention held at Tecumseh, Mich., June 6 and 7, 1889. Supplement to the Report of the Michigan State Board of Health for the year 1889. No. 302. Darius D. Thorp, Lansing, 1889.

Proceedings and Addresses at a Sanitary Convention held at Otsego, Mich., May 2 and 3, 1889. Supplement to the Report of the Michigan State Board of Health for the year 1889. No. 298. Darius D. Thorp, Lansing, 1889.

EUCALYPTUS leaves reduced to coarse powder, like smoking tobacco, and smoked in a common clay pipe, the smoke being drawn into the lungs and expelled through the nose, have marked curative effects in nasal and bronchial catarrh.—*Ind. Pharm.*

PROF. SCHRIMMER advises (*Wien. Med. Woch.*. No. 8, 1889) injections of the salicylate in both acute and chronic gonorrhœa.

℞.—Salicylate of mercury . . . . . gr. $\frac{1}{6}$.
Distilled water . . . . . ℥iii.—M.
Sig.—Inject three times a day.

The Medical Digest.

Dr. Scalgi, of Rome, recommends for antisepsis, very weak solutions of mercuric chloride at a temperature of 40 or 50 degrees C. as being more active than ordinary solutions now used in surgery.

These, according to the Annales d'Orthopedie, produce at the surface of the wound, a coagulation with union by first intention. The strength employed is one to 10,000 or 20,000.

Hypnotic Eccentricities. — Tessié communicated the following to the Congress for Forensic Medicine: He hypnotised the patient and suggested to him, "The right ring finger represents lasciviousness, the left the opposite." On being aroused, he grasped the right finger, producing an erotic condition. While he was preparing to pollute himself, Tessié grasped the left finger, when patient desisted, and the combat between the contending emotions was depicted in his face. When both fingers were grasped, the patient became perplexed. The most incredible point of the communication is the statement that an extreme erotic condition, with consequent indulgences, was aroused a day later by the accidental pressure of the right finger by a friend.

—*Int. Klin. Rundschau.*

Treatment of Iodism.—The origin and treatment of iodism is the subject of an essay by Roehmann and Malachowski, who regard the manifestations of intense irritation of the mucous membrane, which so frequently follow the administration of small as well as large doses of iodine, due to free iodine in the system. It is necessary for this development that nitrites should circulate in the organism and that the reaction of the respective mucous membrane should not be alkaline. Hence, the authors' attempt by administering 150 to 180 grs. bicarbonate of soda in two doses daily, to render the mucous membrane alkaline. By this treatment, pursued since 1887, they have succeeded not only in ameliorating the most intense iodic irritations, but in removing the milder ones entirely.

—*Therap. Monatsh.*, 1889.

In the *Annales d'Orthopedie et de Chirurgie*, Naples, Italy, Poncet of Lyons speaks very favorably of osseous grafting, which he has studied with special care. His first case was a boy who had lost his right tibia from osteo-periostitis, into the place of which he transplanted pieces of bone taken from other animals. Astraight well-formed bone was the result, although shorter than the sound one.

With years, the shortness became apparent, because, while the left tibia grew in length, the other remained stationary, the cartilage of the epiphysis, to which bone growth is due in a longitudinal direction, being destroyed.

He advises also replantation in large losses of bony substance, as, for example, after extraction of large sequestra. Here the grafting must be done with small pieces of bones of cancellous structure only, using, at the same time all antiseptic precautions.

Internal Use of Turpentine in Diphtheria. —Dr. Peñalva, of South America, had good results from this treatment. In five pronounced cases of severe type, improvement began on the second day. He uses it in mucilage with syrup tolu. Dr. Lewantaner, of Constantinople, who has for two years advocated large doses of turpentine in croup, has recently published two cases which apparently were only to be saved by tracheotomy, but which yielded to one teaspoonful of pure turpentine. This produced severe cough, by which croupous membranes were excreted. The dose may be repeated once or twice, and followed by a mixture of smaller quantities.

—*Deut. Med. Zeit.*

An Epidemic of Phthisis is reported by Marfan, who observed fourteen deaths from among twenty-two employes in an office during five years. The cases are traced to one employe who, at forty years, died of phthisis, after twenty-four years' employment. He coughed and expectorated a great deal for three years. The office occupied by these men only admitted 10 cubic meters air for each individual; ventilation and light were bad. The floor was uneven, full of crevices and cracks, and was not kept clean. *All employees spat upon the floor.* The author has no doubt that tuber bacilli were present in the dust arising from sweeping done in the presence of the employes. He was prevented from demonstrating this fact, because the place had been thoroughly swept when he called. The predisposing element of poverty (the small incomes), and inhygienic dwellings, doubtless played an important *rôle.*—*W. Med. Presse.*

Prof. Henoch on Diphtheria reports on one hundred and ninety-two cases. In many cases it is possible to distinguish diphtheria from angina lacunaris only after prolonged observation. The diagnosis is clear only when all or several cardinal symptoms are present. Bilateral deposit, involvement of the soft palate, vulva, etc.—albuminuria, nasal infection. Enlarged glands and fever are present in angina, also. In 110 out of 152 cases, the pharynx alone was affected; in 82 cases the larynx was involved; of the latter, 12 were not operated on on account of sepsis and collapse, or severe lung complications. Intubation was not used; 9 of 70 tracheotomies were saved. More than half the children suffered from tuberculosis and rachitis, and under two and a half years. Croup is to be distinguished from diphtheria. Out of 36 cases of croup, 24 per cent. were saved by tracheotomy; of the 110 pharyngeal cases, 32 died. Fever proves nothing. One septic case, with many petechiæ, was free from fever till it died. Deposits on the hard palate, cheeks, tongue, and lips, are bad omens. Deposit on the nose he does not regard as so serious. Uræmia is very sure. Nephritis occurs usually from the third to the fifth day, with casts, epithelial, but few red blood globules (as in scarlatina).

Croupy cough and stridor do not indicate operation of therapeutics. He can say but little. He has tried all the new remedies; in the severe cases all failed.

—*Int. Klin. Rundschau.*

Medical News and Miscellany

FRANCE has a sleeping girl.

BLOCKLEY gas pipes are on a strike.

Russia's Czar now takes chloral as a nerve bracer.

DIPHTHERIA is epidemic in portions of Lancaster County.

"ESCULENT REPOSITORY" is the sign of a grocer in this city.

DR. DERCUM has recovered from an attack of typhoid fever.

DR. W. F. DECKER was attacked and beaten by an insane patient.

DR. WILLIAM ATLEE, of Lancaster, died of typhoid fever in Washington, D. C.

THE will of William A. M. Fuller bequeaths $1,000 to the Episcopal Hospital.

CORN canned by the salicylic acid process poisoned a child in Chester County.

DR. J. P. HOFFA, of Montour County, has been in Philadelphia for a short visit.

THE death of fourteen infants in London last week were attributed to "overlaying."

AS a cure for insomnia a Brooklyn clergyman exerts will-power with unfailing success.

DR. S. T. MAYER has resigned his place as vaccine physician in the Twenty-ninth Ward.

THE Chinese eat pumpkin seeds between the courses at dinner as an appetizer and digester.

A POOL of water in a lot up town has flooded out twenty-three houses and caused sickness in the neighborhood.

THE Russian epidemic of influenza that affects St. Petersburg from Czar to peasant, is said to be rapidly spreading.

NEAR-SIGHTEDNESS affects France as well as Germany; 46 per cent. of the French college seniors having myopic vision.

THE Norwegians are the longest lived people in the world, there being a very slight mortality among children in that microbe-free land.

A BOSTON doctor has been arrested for failing to report a case of small-pox in a crowded tenement house, until over a week had elapsed.

DR. A. E. ROUSSEL has been appointed Demonstrator of Physical Diagnosis at the Medico-Chirurgical College, in place of Dr. Aulde, resigned.

A STUDENT in the Maryland College of Pharmacy possesses a wonderful magnetic power which enables him to lift heavy objects with the tips of his fingers.

THE *Sanitary News* warns persons who bite off the ends of silk thread, of the danger of lead poisoning, as the silk is soaked in acetate of lead to increase the weight.

HABITUAL drunkards in Norway and Sweden are put in jail and fed entirely on bread steeped in wine, till they become sickened and are glad to live as total abstainers.

BY a gift of $5,000 to the Presbyterian Hospital. Mrs. E. P. Baugh and son (Chauncey Baugh) have endowed a free bed in that institution in memory of the late Mr. Baugh.

DR. MORITZ HAY, of Vienna, has been awarded a gold medal in the Section of Public Health, and a silver medal in that of Medicine, at the Paris Exhibition, for his specimens of vaccine.

A BOSTON man fell over the stair railing in Odd Fellows Hall and swallowed his tongue, which the shock forced down his throat. He was an odd fellow indeed, to be so scared by the goat.

DR. GORTER is said to have received $17,000 in settlement of his bill for attending Robert Garrett on his trip around the world.

It is expensive to be a millionaire.

REV. MR. SWINDELLS becoming wearied at the delay in completion of the Methodist Hospital, has tendered his resignation as superintendent of that institution and will return to the pulpit.

THE danger of overhead wires for electric lights has again been demonstrated by the death of a New York clerk, who came in contact with a wire which supplied electricity to a lamp in front of his store.

A SUBURBAN storekeeper who hung out a sign that a boy was wanted, was surprised by a literal interpretation on his return after a temporary absence, when a foundling lay on his counter and his sign had been removed.

THE British ship Germanic from Cebu, Philippine Islands, which has just arrived at the breakwater, having had a case of the Asiatic cholera last July, will be disinfected and fumigated before she is allowed to approach the city.

DR. MCCOOK, of this city, is one of the judges to award three prizes offered by R. H. Lamborn for the best three essays "based on original observations and experiments on the destruction of mosquitoes and flies by other insects."

DR. APOSTOLI, in giving the results of his treatment with electricity in gynæcological cases, shows that in many instances extreme sensitiveness from pain can be relieved by a few minutes' application of the inducted current.

A CINCINNATI lady is applying for a divorce on the grounds that her husband, a drunkard, after threatening her life, in order to torture her, compelled her to sleep beside a skeleton that he had brought home from the medical college in which he was employed.

OPERATING tables in France are so constructed that the lower end can be elevated at a moment's notice, and thus when there is danger of heart failure, the patient can be held head downward till restored.

The Daggett table has this mechanism most ingeniously applied.

This week has witnessed the great festival held in behalf of the Medico-Chirurgical Hospital. The Academy of Music has been nightly crowded to the doors, and thousands of persons have been delighted by the novel and beautiful spectacles provided by the Managers. The Medico-Chirurgical entertainments have become recognized as a feature of the winter, having now been held for five successive seasons, with constantly increasing magnitude, until they have now the credit of holding the greatest fair which has been seen in Philadelphia since the Sanitary Fairs during the war. Whether they can outdo their present exploit seems doubtful. We understand that the hospital has cleared a very large sum.

To Contributors and Correspondents.

All articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Clinical Lectures.

CHRONIC LEAD POISONING.[1]

BY WILLIAM F. WAUGH, M.D.,

Professor of Principles and Practice of Medicine and of Clinical Medicine in the Medico-Chirurgical College of Philadelphia.

THIS patient comes before us suffering from lead-poisoning. He is thirty-six years of age; has followed the occupation of painting for eighteen years. Ten years ago he experienced the first symptoms of poisoning in an attack of what is known as painters', or lead, colic. He had, therefore, followed his business eight years before suffering any evil effects from it, in which respect he was more fortunate than the majority of those engaged in this business, since, they generally experience lead colic long before that. Had now our patient abstained from dirty habits while engaged in his business, he would have averted what befell him four years later, paralysis of the extensor muscles of the forearm, for which he to-day presents himself here for treatment. Observe the pendant position of the hand; known as wrist-drop.

The dirty habits I referred to as being conducive to lead poisoning, are tobacco chewing and lunch eating with unwashed hands. These men, while engaged at their work, will take their tobacco with their hands all besmeared with paint. Necessarily, a plug, repeatedly handled in this wise through the day, becomes coated with more or less paint. Then, again, they stroke their moustaches with paint smeared fingers during and after eating, and when they go to their homes a mere washing of the hands suffices them. They never think of using a nail brush to remove from under the nails the paint lodged there. All these unclean habits are means of conveying lead mechanically to the mouth, and thence it gets into the system. We find, upon inquiry, our patient to be deficient in these details of cleanliness, and that he is also a tobacco chewer. Hence we say it is his own fault, and not his trade's, that he is now a sufferer from plumbism.

Looking into his mouth, I observe a blue line along the edges of the gums, immediately adjoining the teeth. It is called the lead line, and is produced by a deposition of lead in the tissues of that part. The line is largely determined by the amount of tartar present, as the decomposing matters mingled with it evolve hydrogen sulphide, which is supposed to react upon the lead, precipitating the sulphide of lead. The line is pathognomonic of the impregnation of the system with lead.

Now, what as to the treatment? The addition of a few drops of sulphuric acid to his drinking water is a good preventive measure, since the lead which may yet incidentally get into his mouth and be swallowed with the saliva, will thus be converted into insoluble sulphate of lead, which, it is believed, will do him no harm. It is not advisable, however, to continue the use of sulphuric acid too long. Though it stimulates at first, its continued use gives rise to debility. Absolute cleanliness is the best preventive treatment you can recommend, providing your patient cannot conveniently change his occupation.

As to the curative treatment of this affection, you must understand the pathological conditions involved

[1] Abstract of a clinical lecture delivered at the Medico-Chirurgical College.

before you can treat it scientifically. The muscular layer of the intestines is in a state of paralysis, as well as the extensor muscles of the forearm; both parts being affected through the nervous system, which has been pathologically impressed by the lead deposited in the tissues. In the intestines, however, there is not only a disturbance of the motor nerves—hypercinesis—interfering with regular peristalsis, but also an affection of the sensory nerves—hyperæsthesia. The paralysis of the muscular coat gives rise to much constipation, the fæcal matter and its gaseous emanations act as irritants in the contracted intestine, which, owing to this hyperæsthetic condition, become the seat of more excruciating pain than they are in an ordinary colic. It is important to remember this pathology, because it explains an apparent therapeutic inconsistency in the treatment of this disease. Now, alum is given, and you ask, why give alum, which is an astringent and induces constipation, of which the patient complains? That's homœopathy, you say. Not so. It is true that alum is an astringent, but we give it because it relieves the paralysis of the muscular coat of the intestines, and, in thus restoring their normal function, makes possible regular evacuations. The lead is deposited in the tissues, being absorbed along the course of the alimentary tract or through the lungs in a finely divided state. The rationale of the treatment then is to redissolve it, loosen it up and get it out of the system through the emunctories. To this end we give five grs. of the iodide of potassium four times a day, increasing the dose each day, to the verge of toleration. We give the iodide of potassium to get iodine into the system; but if given too long, the base, potassium, interferes with digestion. Should we have evidence of this in our patient, we will substitute hydriodic acid, a recently introduced but excellent form for administering iodine. When the destructive action of the iodine has reached that degree at which counter-action is indicated, we shall prescribe some constructive remedy; none better than cod-liver oil, when given for a long time in tablespoonful doses three times a day, To the paralyzed extensors we will apply faradization. The disease is an absolutely preventable one among painters if they take the necessary preventive measures.

To Administer Guaiac.—Place three teaspoonfuls of granulated sugar in a cup, add one teaspoonful of ammoniated tincture of guaiac; mix, and add a tablespoonful of water, mixing again. This makes an agreeable dose, which can be taken by a child.

—*Med. World.*

Poisoning by Bonbon Wrappers (Dr. Van Hamel Roos).—Several children at Hillegom became suddenly sick (vomiting, diarrhœa) after having eaten bonbons. A careful search proved that the paper covering the candies had been the cause of the accident.

The sugar, in melting, had become mixed with the coloring matter (arsenite of copper). The paper contained twenty per cent.—*Journal d'Hygiene.*

A RATIONAL TREATMENT FOR DIPHTHERIA.[1]

By A. E. HOADLEY, M.D.,
Professor of Orthopedics, College of Physicians and Surgeons, Chicago; Professor of Surgery in Chicago Polyclinic, etc.

THE plan of treatment to which I wish to call attention, has in my hands for years been uniformly successful, and in every instance, where thoroughly practised, perfectly satisfactory in its results. Where failure has been recorded, it has been no fault of the plan of treatment, but of some detail of its administration. I have come to regard it after years of experience as infallible. Here let me state that in speaking of the treatment of diphtheria, I have no reference whatever to the complications and sequelæ, and when I say diphtheria I refer to the white pellicle or substance that grows in the throat upon the surface of the mucous membrane. I mean that and nothing more. In advocating a treatment for this condition, the plan and the remedies and general condition of the patient are comprehended. No one remedy is advocated to the exclusion of any others that may have equal merit. The treatment is based on scientific principles, as far as science can at present apply to diphtheria. Such remedies are used that will by their known therapeutic effects meet the required indications. If the method of its use be correct as to time, quantity, concentration, and combination, there can be no doubt about the results.

You may say that if I can do this for diphtheria, I must have settled the very vexed and much discussed question of its etiology. To which I make answer that I have settled that question to my own satisfaction, but can only offer you circumstantial evidence in proof of the correctness of my views—namely, that when I apply treatment in accordance with these views, it is reliable. It has occasionally happened that I thought I had applied the treatment and found later, perhaps too late, that I had not, or that it was deficient in some detail; some circumstance over which I had at the time no control, had rendered the treatment futile. Such accidents as faulty judgment, negligence, forgetfulness, misunderstanding, inability to carry out the details of the treatment from any cause whatever, are no faults of the plan of treatment, if for such reasons it fails. It is simply this, the treatment that might have been successful was not applied. Therefore, with implicit confidence in the plan of treatment, a confidence born of years of experience, in any given case, it is only necessary to see that it is instituted in a manner that no detail shall be omitted or misunderstood, to be sure that success will be the inevitable result.

---

[1] This paper was read before the Chicago Medical Society under the title of "An Infallible Treatment for Diphtheria." The title was about the only part of the paper that received attention. Its condemnation was unqualified and vigorous, and almost universal. It was very apparent that the Society was not willing to distinguish between diphtheria and the complications and sequelæ, for which reason it was thought best to change.—Author.

In regard to the etiology of diphtheria: From the literature on the subject, from my own observations, verified by the uniform success of my plan of treatment, I conclude, that diphtheria is in all cases primarily local, and for obvious reasons in the great majority of cases it commences in the throat. It consists invariably of mixed micro-organisms; but there is no specific organism; and there is no organism that can constantly be found in diphtheria, except the same can be found normally in the mouth. That diphtheria does exist in infinite varieties, determined by the combinations of the organisms composing it; that the combination of organisms determines the amount and quantity of the alkaloidal poisons produced; that some of the organisms necessary to the formation of diphtheria, exist normally in the mouth and are harmless. That these organisms can be transmitted by contact from patient to patient, as mixed organisms, and as such propagate or form new combinations, more or less virulent. That single varieties of organisms may gain access to a patient's throat and there form combinations of varying qualities; that these organisms may exist in the throat for some time, even days, in quantities sufficient to produce constitutional symptoms, without being visible even upon the surface of the tonsil, and certainly so if they occupy the follicles, which is common. That the constitutional symptoms are due to the absorption of ptomaines that have been elaborated in the diphtheritic mass; that the subsequent changes in the blood and tissues, especially the nervous system, are due to the more or less direct effect of the ptomaines; that the ptomaines are given off from the free surface of the diphtheritic patch, and find their way into the system by way of the alimentary canal and lungs in far greater abundance than those absorbed at the seat of the diphtheria; that the quality and quantity of the ptomaines vary greatly, according to the particular (unclassified) quality of diphtheria present. That the infectiousness of diphtheria is in proportion to the energy and toxic power of the ptomaines, although the ptomaines themselves do not transmit the disease. That this disease has no period of incubation or latent stage; that one attack of the disease gives no immunity. That abscesses, as a complication, alwas depend upon the absorption of pus microbes. Diphtheria does not predispose to suppuration.

Of the foregoing propositions, some are already accepted by the profession, and others are not and possibly never will be, or, should they all be accepted, they may not be capable of demonstration to the extent herein indicated. Be that as it may, it is upon these principles that the treatment is founded; although, as a matter of fact, the treatment was adopted years ago, and has, so to speak, founded the principles which have recently taken definite shape in my own mind. The harmony of these principles with the treatment that was adopted so many years ago, convinces me that they are in the main correct.

Twelve or thirteen years ago I became thoroughly disgusted with the then standard gargle for all cases of sore throat, viz.: *the chlorate of potash solution, with tincture of iron.* I could never prescribe it without trouble. The patients would either refuse to use it, or, what amounted to the same thing, would use it but two or three times a day. Then the serious effects upon the teeth and so forth, and I decided to adopt some other formula to take its place, and after some study and research, I decided upon the following, and declared that I would never use the iron and potash gargle again. The formula as adopted at that time, and which I have never found necessary to change, except in minor respects, is as follows:

℞.—Potassii chlorat . . . . . ʒ j.
Tr. myrrhæ . . . . . ʒ iij.
Acid carbolici . . . . . gtt. iv.
Mel. despumat . . . . . ʒ iv.
Aquæ . . . . . ad. q. s. ʒ iv.
M.—Ft. mistura.
S. Fifteen drops every half hour.

The first dose or two of this medicine is quite bitter, but very soon the slight amount of carbolic acid present paralyzes the sense of taste, and it is no longer objectionable. The myrrh is the antiseptic and disinfectant; it is soothing, stimulant, slightly astringent, and tonic to the mucous membrane, and it can be used freely in the nasal passages, in the throat, and can be inhaled into the lungs every fifteen minutes for days with perfect safety. Aside from its recognized medical properties, it has unquestionably the power to completely suspend the elaboration of ptomaines in a diphtheritic mass; and here let me say, that I have no doubt but that there are a great many other remedies that can do the same thing, but myrrh has stood the test for many years, and given perfect satisfaction, I want no better, and, therefore, I want no other. The only mission of carbolic acid is to relieve pain and soreness, which it does admirably in the throat, if this weak solution is given as often as once in thirty minutes, but not otherwise. When there is a desire to dissolve diphtheritic membrane, or if the mixture smarts unpleasantly in the mouth or throat, then the solution of chlorate of potash should be changed for lime water. This more readily dissolves the membrane, and is also painless after the potash has become irritative. In place of the honey I have often used glycerine, and many times druggists have used molasses and syrup for me as a substitute, but I prefer the honey. When this formula is properly compounded of good materials, it gives a mixture of a light creamy brown color, very soft in tint, and by these qualities of color you may recognize the quality of the medicine. This formula, as prepared by different druggists, varies very much, and as the color and softness of texture of color varies, so does it vary from the best quality. Some druggists will pour the tincture of myrrh into the bottle without any effort to form a good mixture, and the result is that the gum myrrh is deposited in reddish brown masses around the upper end of the bottle; then, of course, the mixture is worthless. Then, again, some druggists, desirous of making an elegant mixture, will filter, and of course remove all of the myrrh, except the odor, and render the medicine practically inert.

In the treatment of recent cases of diphtheria of

moderately severe type, where there is marked constitutional symptoms, with a well-developed and goodly patch of exudate, as it is called, upon both sides of the throat, so long as it has not already extended so high that its upper limit is out of sight, or involved the larynx below, and with the patient old enough to do with certainty as required, it is only necessary to order the mistura myrrh. cum. pot. chlor. to be given in fifteen-drop doses every half hour, day and night, asleep or awake, until the diphtheria falls off and the patient well. The medicine should be retained in the throat each time as long as possible, and then swallowed, and occasionally, say every hour or two, a full teaspoonful of the medicine should be gargled thoroughly and spit out. If the child is very young and the patches of diphtheria small, and in such a position that they will certainly be bathed each time the remedy is swallowed, then the fifteen drops every half-hour, day and night, asleep or awake, will be quite sufficient. Should the larynx be threatened or involved, or the diphtheria extend up behind the palate, or the nasal passages involved, or likely to be involved, it will be necessary to use the medicine through the nose and mouth by means of the atomizer every half hour, day and night, and if the larynx is involved, the spray must be inhaled at each administration. The best atomizer at present in the market, to my knowledge, is the Davidson No. 59. It will deliver a coarse and abundant spray of this remedy, which is quite essential to its thorough application. In the more severe cases, and especially if they are likely to have diphtheria in the throat for three or four days, it is probably advantageous to give tincture of iron in moderate doses every three hours, together with judicious feeding. No other remedies will be necessary. Just where the pseudo membrane exists at the time of the administration of the first dose of medicine, there it will stay. Not one particle of advance in the spread of the disease will take place after the first thorough application, provided the applications be repeated at intervals not exceeding thirty minutes; forty-five minutes will not do; thirty minutes is the longest interval that may be allowed to elapse while diphtheria exists. The patch will then begin to grow thicker and thicker, and become undermined at its margins, all surrounding inflammation will disappear rapidly, and in the average case the diphtheria, if seen early and thoroughly treated, will fall off in a mass, leaving the mucous membrane quite clean and perfectly well in appearance. Within an hour or two after the treatment is commenced, the patient will be greatly relieved, and in eight or ten hours the temperature is usually about normal, although the diphtheria may appear as formidable as ever. The moderately severe case where the false membrane is forming rapidly with great constitutional disturbance, rarely requires more than forty-eight hours for the complete removal of the disease, and very frequently twelve hours are sufficient. It is to be understood that these results are to be expected in cases that are seen early. It must also be understood that it is not the object of the treatment to remove primarily the membrane. The primary effect is to prevent the further extension of the disease, and the formation of the deadly ptomaines. The diphtheritic mass is rendered inert, and can do no harm so long as it is continually bathed upon all sides by the medicine, unless by the volume it shuts off the post-nasal space or other spaces, and then in that direction spreads, and the new extension produces poison, the absorption of which will be disastrous. To obviate such a contingency in the rapidly forming masses, the spray should be freely used through the nostrils. In severe cases the thick masses should be broken down with the finger very carefully, lest the mucous membrane be injured, and invite the entrance of pus microbes. After breaking a large mass, the atomizer should be used very thoroughly and repeated every ten minutes for five or six times, and the myrrh mixture should contain bichloride of mercury 1 to 3000.

Malignant cases or such cases as are expected to be malignant, must be treated in accordance with their severity or expected severity. The iron should be given in maximum doses, and the myrrh mixture used every fifteen minutes, and precede the attack by its administration every half-hour where possible; or, in other words, every patient that is likely to contract the disease should be placed under treatment. The result will be in the majority of the cases no attack, and in those cases that are developed while under treatment, you may rest assured that the treatment has been slack; that there have been intervals of more than a half-hour between the doses of myrrh mixture. It is difficult to have patients that are not sick get the treatment day and night; but where they have so had the treatment I believe it impossible for the disease to develop, no matter of what type. Water is an infallible agent with which to extinguish fire; still, if you set fire to a keg of powde,r you would hardly expect to put it out with water; but, by using the water before the fire, you might control or prevent it. So with these fearfully malignant cases of diphtheria, where they cause death in from twenty-four to thirty-six hours; if they become developed we can hardly expect to cure them by any means. Our best hope with these cases is in prevention. To do this the treatment must be instituted and persevered in with the same regularity by means of the atomizer as we would to cure a case already developed. I have many times tested the prophylactic power of this remedy, and I have yet to see a case develop against the half-hour application of the myrrh mixture. Hourly applications to the throat may protect, but are not reliable. I regard outward applications of every kind positively detrimental in the treatment of diphtheria. I have never allowed them to be used, and when I find a patient with them, they are immediately removed. I am opposed to outward applications as a whole, on general principles, in all sorts of throat troubles, for I am sure that they cause more suffering than they ever relieve, and more diseases than they ever cure. You may have this wholesale statement for what it is worth.

The treatment of complications is another thing. I wish to emphasize the fact (and I believe it is a fact) that no so-called remedy or measure can occupy neutral ground. It is capable of doing good, or else it

will do harm. I do not believe in the old woman's reason for using a remedy: "that it can do no harm." Everything in the way of treatment should be excluded that is not positively known to be of benefit. I have repeatedly been called to children suffering with diphtheria where the means employed to combat the disease were in themselves sufficient to cause the death of the patient had the diphtheria been left out of the question. Swabbing, painting, steaming, spraying, powdering, purging and puking the inside; poulticing, packing hot and cold, wet and dry; lubricating, irritating, vesicating, fumigating and suffocating the outside, and it is only a question of time when the most robust will succumb. I have been asked to suggest, after the above means severally and collectively had been tried and the patient's strength exhausted, as much by the misguided energy of the treatment as by the disease, "What could I suggest?" Another means by which the patient could be further tortured, only to be soon superseded by still another. No; I advise the withdrawal of the allied forces, and leave the disease to fight it in single-handed combat, that the patient's last moments may be a little less terrible. These remarks may seem to many of you uncalled for, but I can assure you that they will strike home to many a good physician and set him to thinking.

I have had physicians declare to me that they had tried my alleged treatment, and that it did not do the least bit of good. The reason that it did not do any good in their cases is because they thought fit to use the remedies in larger doses and less often, and it was not important to disturb the patient if it could only sleep, forgetting that diphtheria grows best while the patient sleeps. Then, again, it would not cause the diphtheria to disappear like magic, nor would it reduce the temperature against the combined influences of diphtheria, poultices, packs, and an elevated temperature saturated with the same poisonous vapor, or perhaps while it was sweltering in a lime steam.

I wish now to cite a few cases in exemplification of the plan of treatment that I have dared to intimate as infallible.

CASE I.—George K., a lad of five years, was brought to my office by his mother at eleven o'clock A.M. He was taken sick in the preceding night with chills, high fever and sore throat. An examination revealed a temperature of 103½°, very rapid pulse, fauces dark red and seemed very sore. The child appeared to be very sick. I made a diagnosis of diphtheria, although there was none to be seen, and ordered the myrrh mixture to be given every half hour all day and night. Before bedtime, however, the child was, as the mother stated, quite well, throat and all, and the remedy was discontinued, In the night the child was again attacked with headache, chills, fever, and sore throat, and the remedy was indifferently resumed, being given occasionally until morning, when I was summoned. On arriving I found a much worse condition than on the previous forenoon, for both lateral aspects of the throat were invested with diphtheria, and the constitutional disturbance was severe. This was 8 A.M. The medicine was, with emphasis, ordered to be given in fifteen-drop doses every twenty minutes all day and night, until I again saw the case. On the following morning I saw the boy and have every reason to believe that my orders were obeyed, for the child appeared to be perfectly well, and on inspection the throat gave no evidence that he had ever been sick. He was ordered to have the medicine every half hour through that day and night and then discontinued. The myrrh mixture was the only remedy used in his case. There were other children, but no other cases; they were all required to take the medicine while in the house, which may have protected them. This is a good illustration of what could be called a constitutional case with a local manifestation, inasmuch as there was no diphtheria in the throat for twenty-four hours at least, subsequent to the first constitutional manifestation, and yet by local treatment it was promptly controlled during a few hours on the first day, and then after a renewed attack was completely cured on the second day. With these facts before me, I am constrained to believe the disease a local one.

CASE II.—Laura F., three and one-half years, developed rapidly a very severe form of the disease. I saw the case in the evening; twelve hours after the initial symptoms, the throat was the seat of a very angry and apparently painful inflammation. The fauces were almost entirely covered with diphtheria. The tonsils were so large that they together with the diphtheria almost occluded the passage. The constitutional symptoms were in keeping with this very severe, and you might think, unpromising condition of the throat since the patient was so young. Myrrh mixture was the only medicine used. The atomizer was not used, although it was impossible to see the limits of the exudate. Fifteen drops every half hour day and night, whether asleep or awake, for thirty-eight hours cleaned the throat apparently, dissipated the inflammation and restored the child to apparent health. Ordered the medicine continued through the balance of the day and all night, and, if everything seemed well in the morning, to continue for a day and night every hour. In the forenoon of the next day, I was sent for, and on arriving I was informed after some questioning that relentless slumber had taken possession of the attendants and the medicine had been omitted for two or three hours during the night, and that as a result the child appeared quite as sick as on my previous visit. The diphtheria was even more extensive, although the swelling and inflammation were also severe. The treatment, of course, was resumed and given a little oftener and persevered with for about forty-eight hours before the throat was again clear. The patient during the greater part of this time had a low temperature, and was quite comfortable. The medicine was continued every half hour for forty-eight hours longer, lest the disease should again recur. It is no hardship to a child to be required to swallow medicine every half hour; if they are sleepy they are hardly conscious of the disturbance. The atomizer is the greatest annoyance to the little sufferers, still they sleep a half an hour at a time, which is quite sufficient. I think that the lesson taught in this case is that diphtheria is a local disease.

CASE III.—Effie H., a girl of eight years, had a very severe type of the disease, and the fauces were lined with diphtheria before I saw her at 9 A.M. The medicine was ordered given by the mouth in fifteen drop doses every half hour, and in evening of the same day she was very comfortable, temperature nearly normal and still her throat was lined with diphtheria, in extent exactly equal to what it was when she began the use of the medicine in the morning, but the patches were much thicker and whiter. On the following morning they were less extensive, beginning to be ragged, and where their continuity was undisturbed were from one-eighth to three-sixteenths of an inch thick. In the evening, thirty-six hours after treatment commenced, there were only here and there small ragged patches of the diphtheria left. The mother was cautioned that during the night she must under no circumstances omit the medicine, and she gave it regularly every half hour until five o'clock A.M., when she fell asleep and gave the next dose at 6.30, thus missing, as she affirmed, but two doses, and she was a lady of whose truthfulness I had no doubt. Be that as it may the interval of omission was a very short one. During this brief interval the disease was again in possession, spreading over the entire surface before involved, and extending up behind the soft palate out of sight, and down to the larynx was a thin film of diphtheria, and the constitutional symptoms were very severe at 9 A.M., the time of my visit. The atomizer was called into use and for three or four hours was used every fifteen minutes, when there was marked improvement again in the constitutional condition, and the time extended to intervals of half an hour and continued for some time after the throat was again clear, which required about forty eight hours. Tincture of iron, ten drops every three hours, was used with this case from the commencement, as there seemed to be an indication for it in the child's previous habit. This case so briefly noticed is interesting from the fact that it was very rapid in its development, both primarily and secondarily, and in the relapse the larynx was threatened, and the nasal cavity invaded in a remarkably short space of time, one hour and a half. It is also interesting to observe with what wonderful promptness it was controlled with the atomizer.

CASES IV AND V.—Hilda H., a girl, aged seven years, contracted malignant diphtheria from a younger sister, of four years, who died of the disease in about forty hours. It is fair to suppose this the origin, although she was attacked but a few hours later than her sister. A baby of two years happened to be, or was, at the time of the outbreak of the disease, put away from the house, and so for a few days escaped. These children were under the care of a very competent physician, one who enjoys a very high professional reputation, and justly so. He was faithful in his attendance, and earnest in his endeavor to control the dread disease. When the first child died the physician informed the parents that it was only a question of a few hours before the other child would also die; that it was impossible to control the disease, and that she was fast sinking under its poison. Word was left with a neighbor to have me see the patient. I declined this invitation, stating that if that physician pronounced the case a hopeless one, it would be useless for me to attend. A few hours later, however, I was again summoned by a special messenger, who stated that the physician had retired from the case, and that I was earnestly desired to see the girl before she died. I immediately responded, and, as might be supposed, found the patient in an extreme condition. The first thing that attracted my attention on entering was that restlessness so characteristic of the overwhelming influence of the poison. The child was breathing with difficulty, on account of the occlusion of the fauces and pharynx; the head was extended for the purpose, partly, of facilitating respiration; but on removing the wraps from the head, and the applications from the neck, another reason was found for the extended head. The neck was badly swollen and of brawny hardness, not particularly tender to the touch. An inspection of the fauces was sickening; an intensely putrid penetrating and persistent odor overwhelmed me, and I felt inclined to make a hurried retreat. I could not sit down or touch an article in the room, and I never experienced greater relief from something to be dreaded than I did when I again gained the open air. I stayed, however, long enough to order the myrrh mixture to be given in teaspoonful doses, for a gargle, every half hour, after gargling to be spit out, as I understood that the child was an adept at gargling, and to swallow fifteen drops every half hour in the intervals of gargling. The next morning the child was very much better, quiet, swelling was subsiding, head had assumed the natural position, breathing quite easy. The offensive odor from the throat was entirely gone, although the throat was still full of diphtheria; but now it was white, whereas, the day before it was black; probably the effect of the previous applications. The little patient could plainly articulate that she felt first rate, while on the previous day it was almost impossible for her to form a single word. I now crushed under my finger the prominent masses of diphtheria, some of which came out of her mouth; the rest that were detached were swallowed. This procedure I would not have done on the day before, lest the patient be immediately poisoned to death; but after the masses had been robbed of their ptomaines, or the formation suspended, and those that did exist had been either absorbed, dissipated or neutralized, there was no danger from swallowing it. Immediately after thus gently crushing the diphtheria, the child was required to gargle a solution of bichloride, 1–2000, every fifteen minutes for four times, and then continue with the myrrh mixture alone. Tincture of iron was administered in ten-drop doses every three hours. No further unpleasant symptoms occurred. In about three days the throat was quite well and clean, and no complications of any kind followed. Towards the close of one week from the convalescence of this patient, the mother began visiting her baby, who was domiciled with a neighbor under the same roof in another flat, and taking the myrrh mixture during the day as a prophylactic. One night, after one of the mother's visits, the child was taken very ill, and the good neighbor labored earnestly

with the sick child until morning, not for once thinking that it would be proper to give the throat medicine. In the morning the mother was summoned, who in turn summoned me, and in the meantime commenced the medicine. This child was suffering with malignant diphtheria, and no evidence lacking; and still in twenty-four hours there was not a trace of the disease left. The medicine was, of course, continued for some time, to prevent a recurrence. After the medicine was discontinued some three days, I think, the child was taken home, and again had an attack which was as severe as the first, and recovered as promptly under the use of the myrrh mixture, so I was informed. I did not see the child during the second attack. In the case of the first patient, although the disease was most malignant and far advanced, still the membrane had not extended in any direction beyond the reach of the medicine as used by gargle, therefore, it was possible to immediately stop the process of poisoning, and give the child a chance to eliminate, which she promptly took advantage of. I have had quite a number of cases of malignant diphtheria recover under similar circumstances with similar conditions prior to the commencement of the myrrh mixture, except for the fact that the most of them were given large quantities of whisky in addition.

Cases VI to XI. This will constitute a group of cases of malignant diphtheria, and be described collectively as far as possible. Mr. and Mrs. B. were the proud possessors of a very interesting family of seven children, embracing twins and ranging in ages from three to fifteen years. There was but one boy, who was twelve years old, and the only one to escape. The youngest child was the first to contract the disease. It proved to be a malignant form, and she expired within two days. Three other children, the twins, age ten, and the five year old, were simultaneously attacked on the second day. They all gave unmistakable evidence that they had contracted the disease in its malignant form; the suddenness of the attack, the rapidity of its development and the energy of its course left no doubt. A homœopathic physician was in charge until after the death of the first child, when he was, no doubt, greatly relieved by being very courteously retired from the case, and I very reluctantly accepted the responsibility. The treatment prior to my attendance seemed to have not the slighest influence to retard the onward march of the diphtheria. Permanganate of potash in solution, used with the atomizer, was the disinfectant employed. This was used often and thoroughly, every hour, I think; but its effects upon the disease, if any, were so slight that they could not be appreciated. At my first visit, which was some hours after the last visit of the retiring physician, the situation was very striking. They had decided upon a change of physicians. In the interval they had become terror-stricken. They had practically abandoned hope, and were indeed like a ship without a helm; yet they went on in a half-dazed kind of way with the atomizer, and sprayed the face as much as the throat, until the faces upon whom they were using it were of a dark bronze color, stained by the permanganate. In one the throat only was involved; in the other two the nasal cavities were already invaded; in one the larynx was involved sufficiently to affect the voice. The constitutional condition in all was alarming. It was a question whether they could recover, even though the poisoning processes were immediately stopped. In two, the youngest and one of the twins, the necks were swelled, full, smooth and boggy; their heads were extended to facilitate respiration. One of the twins seemed to be the worst, as she had nasal, pharyngeal, faucial and laryngeal diphtheria, with a swelled neck, very restless and obtuse mental condition, with complete inability to swallow. Tincture of iron every three hours with the myrrh mixture were the only remedies used. The alcohol was withdrawn, the applications removed, and the parents instructed to use the myrrh mixture containing bichloride 1–4000, with the atomizer through the nose and mouth every fifteen minutes for the first three hours, when the bichloride should be withdrawn and the remedy continued every twenty minutes all night, and the twin with the laryngeal complication should each time inhale the spray twice at least into the lungs. This required unremitting toil on the part of the attendants; but it was faithfully adhered to, and in the morning every one, patients and attendants, were willing to declare that there had been a wonderful improvement. But now an accident occurred that nearly cost the three lives, and the parents were again frantic. The atomizer that they had been using was inferior, and they thought to get Davidson's, but were given some other make, and this instrument was soon broken, and on returning to the former instrument it could not be made to work. During the interval of an hour or two the medicine was administered in uniform doses every fifteen or twenty minutes, but during this short delay it was apparent that something terrible was going on with the children; they were rapidly growing worse. This was appreciated by the parents, and it was almost impossible to again organize the system of treatment. The five year old child's nose became occluded, and it was with great difficulty that it was again opened. For this purpose the lime water was substituted for the chlorate of potash solution. In another day everything was very satisfactory. The children were taking their food without difficulty, except the twin, who was troubled with fluids regurgitating through the nose. They were playing with pennies and jacks as though nothing had ever been the matter. The older children did all they could to facilitate and render the treatment thorough; but the small child would invariably draw down the ala of the nose, rendering the small meatus nearly impervious, and during the night she would in other ways resist the treatment, so that it had been up to this time a hard fight with her to apply the treatment. The father was the only one that could without assistance accomplish it. But there is a limit to human endurance, and after six days and five nights of unremitting attendance, he found it necessary to retire during the sixth night to get a little sleep, leaving the mother and eldest girl on duty.

The girl was very much opposed through fear to

handle the cases, and the mother essayed to treat the younger child without assistance. In this she failed, but she did not find it out until it was too late to make amends. The nostrils had closed, and were not discovered until her husband again came on duty, and even then she stoutly maintained that they were pervious. At my visit some hours later I made an effort to establish an opening through the nostrils, but soon found this impossible. The entire nasal cavity was blocked full, and the diphtheria was extending into every cell or cavity that was developed in connection with the nose. Treatment was cut off. The disease had barricaded the entrance to treatment, and was master of the situation. Diphtheria never sleeps. The child died in the evening, the direct and unquestionable result of incompetence in the attendant. The twins recovered rapidly, the worst one of the two, although bothered for a few days with regurgitation of fluids through the nose, felt quite well and happy, but rather strangely and inexplicably she retained a patch of diphtheria as large as a nickel in front of the anterior pillar of the fauces on the left side for two or three days after the balance of the throat and nose was well. Finally it fell out, for it left a conical hole fully three-fourths of an inch deep extending behind the tonsil of that side. This supposed patch of diphtheria proved to be a slough. This surface as well as the corresponding surface of the opposite side and the anterior surface of the soft palate was covered when the myrrh treatment was commenced, and all the portions referred to except this were the first to fall off.

It is to be understood that the well children were subjected to the same treatment as a prophylactic, but they only got the medicine during the day, they were allowed to sleep. The second day of my attendance my attention was called to the eight year old girl who was taken violently ill in the night; she had vomited, and when I saw her at 9 A.M., had a temperature of 104°, throat very sore, but did not look bad. A small patch of diphtheria on each side was all that could be seen. The treatment was given every half hour day and night, and in thirty-six hours the throat was clean and the child well. The treatment was continued, however.

The oldest girl during these days had two unmistakable attacks, but they were dissipated in a couple of hours by fifteen minute applications of the myrrh mixture, no membrane ever showing, but each time she developed a high temperature; on one occasion it was 101°.

The boy of twelve years took the medicine regularly during the day, was a large part of the time out of doors, and had no symptoms.

The above cases were all of one character, one quality of infection and unquestionably malignant, and yet the fifteen minute application of the medicine to the entire surface of the diphtheria promptly stopped it, no matter where it was located or how much there was of it, or at what stage of development. This for years has been the uniform result obtained by the frequent application of the myrrh mixture. The detail of first importance in the plan of treatment advocated is the application of the remedy to all parts of the surface of the diphtheria; second, the frequency of the application, and if the applications be made in frequency in proportion to the activity of the disease that exists it can not spread, no matter of what character; and third, the use of myrrh as the chief remedy, although I believe there are other drugs of similar nature that might prove quite as efficacious. And finally the complications that have developed as a result of the diphtheria are in no way influenced by the frequent application of the myrrh mixture to the diphtheria, except to prevent further poisoning. As soon as can be properly tabulated and perfected, statistics will be presented of cases treated by this method.

683 WASHINGTON BOULEVARD.

SURGICAL SHOCK—ITS PATHOLOGY AND TREATMENT.[1]

BY HENRY JARRETT, M.D.,

THE term "shock" was originally employed to designate any case of sudden death or collapse, following an injury or mental emotion. With the increase of physiology, and the advancement of pathology, the term has become more and more definitely associated with the idea of a powerful impression on the nervous system, causing a sudden check to the circulation and depression of the entire functions of the body.

We are all aware that shock arises from either a mental source or the result of a serious bodily injury, as an accident, or the effects of an operation.

There seems to be a special gravity attached to those cases of surgical shock resulting from railway accidents. This may partly be attributed to mental causes, as fright, and, principally, to the general concussion of the body from its suddenly suspended motion.

We observe the pallor and coldness of the skin, the weak and rapid pulse, with sub-normal temperature, difficult and labored breathing, anxious expression with extreme restlessness, shown by the tossing about in bed, all serving to indicate a profound impression on the nervous system and lead us to search with interest the pathological conditions. At the post-mortem examination, the one striking phenomenon revealed is the enormous distention of the abdominal vessels. The blood destined for other regions has been practically withdrawn from the general circulation and produced this useless congestion of the abdominal viscera. In ascertaining the probable cause of this, the greatest credit should be given to experimental physiology.

The vessels of the abdominal cavity are under the control of the splanchnic nerves, and with the cardiac plexus of nerves, there exists not only a striking similarity, but close relationship. If the depressor branch of the pneumogastric nerve be divided by stimulation of its central end, there is produced an immediate lowering of the blood pressure in the arteries of the head, neck and extremities, at the same time will be observed a dilatation of the abdominal arteries and congestion of the abdominal viscera.

[1] Read before the Camden City Medical Society, October 10, 1889.

This is undoubtedly owing to an inhibiting or paralyzing effect upon the splanchnic nerves, for should they be cut, and the reflex current severed, the circulation becomes restored, and remains so, although irritation to the depressor nerve be continued. As an additional proof, if a frog be sharply struck upon the abdomen, the splanchnic nerves become paralyzed and produce the same symptons as those arising from irritation of the depressor nerve. This has its analogy in a man who has met with a severe blow on the epigastrium.

In addition to the above-mentioned pathological conditions, there is some congestion of the lungs, which, with the feeble and hastily acting heart, indicates the depressing effect exerted upon the cardiac plexus of nerves. These, together with the splanchnic nerves, suffer most, owing to their position and distribution.

From the general paralysis of the vaso-motor system, all vessels lose their tone, and as a result there is some stagnation of blood in the capillaries.

In short, we may say, that shock is an example of reflex paralysis of the vaso-motor nervous system, and the motor and sensory nerves sharing with it.

The treatment of shock presents two objects:

1. Sustain the lessened vitality; and—

2. If reaction take place, moderate it when excessive.

The first care in a case arising from injury, is to place the patient in a recumbent position, and of course, if there be any source of hemorrhage, it is immediately arrested, if possible. Loosen everything around the neck or chest that could in any way interfere with respiration. In fact, it is better to remove all clothing and wrap him in hot blankets, with bottles of hot water to his extremities, as it tends to elevate the sub-normal temperature. There are many who advocate placing the patient in a hot bath, beginning with a temperature of about 98° F., and gradually increasing to 110° F. By continuing the bath, it has been observed in some cases, that a sub-normal temperature has been elevated to 98.6° F., and the respirations diminished from 36 to 20.

The application of turpentine to the spine, and mustard plasters to the cardiac and epigastric regions, are often of much benefit. For the weak and failing heart at once is suggested the use of alcoholic stimulants. The good effects to be attained by these agents, are often prevented by the large doses given. Instead of accomplishing the desired object, that of stimulation, the opposite is produced, by depressing the system, and making a more difficult reaction. In addition, it should be remembered, that the absorbing qualities of the stomach are much impaired, and an excess of fluid will soon excite vomiting.

From a drachm to a half ounce and six drachms of brandy or whiskey, given every fifteen or thirty minutes, according to the requirement of each case, will answer for the majority of cases. Brandy and whiskey are sometimes given hypodermically, but better results may be obtained from the use of strychninæ sulph., gr. $\frac{1}{40}$–$\frac{1}{20}$, the effect guiding the frequency of administration.

For the failing heart, respiration and general depression of the nervous system, a very effective hypodermic injection can be made by the conjoined use of digitaline, gr. $\frac{1}{100}$, atropine sulph., gr. $\frac{1}{200}$–$\frac{1}{80}$, and strychnine sulph., gr. $\frac{1}{60}$–$\frac{1}{80}$. Ether, when injected beneath the skin, in doses of twenty to sixty minims, will in a few seconds powerfully increase the action of the heart, and, in addition, act as a general stimulant. If there should be much restlessness, an opiate, in the form of morphinæ sulph., will soon answer the purpose. When the patient can swallow, the ammon. carbonat., gr. v to viii, given every hour or two, will produce the most decided effect as a general stimulant.

When reaction takes place, a second indication arises, to moderate it as much as possible and prevent a resulting inflammation. The stimulants should be used with caution, gradually lengthening the interval and afterward diminishing the quantity; but now, nourishment of a more lasting character is required, as animal broths, wine whey, milk, and milk punches.

Anodynes, as morphine and the bromides, are always well borne after severe shock, and they overcome the restlessness which is often present.

To patients requiring an operation, the question occasionally arises, as to the propriety of operating before reaction has taken place. As a general rule it is better to defer operating until reaction is commencing or has taken place, but the main guide is the severity of the shock. If it is so grave as to be questionable whether reaction can set in, every means should be employed to restore him before operating; yet the requirements of the case may be such, as to prevent the giving of two, three, or six hours for reaction. In other words, we will find that each patient must serve a law unto his own requirements.

Hydrotherapeutics.

A PLEA FOR THE PRACTICAL UTILIZATION OF HYDROTHERAPY.[1]

By SIMON BARUCH, M.D.,
Attending Physician New York Juvenile Asylum and Manhattan General Hospital.

[Continued from page 781.]

UNDER this general treatment vomiting ceased entirely; she went to the seaside improved in July, and on her homeward journey called to tell me that she had grown stout and felt perfectly well.

Such cases are infrequent in my experience, but these two illustrate the difference in treatment. No medicinal agent requires so much judicious grading of its dose as the application of water in the treatment of disease. This is one of the obstacles to its general application. For I have known the most intelligent physicians to commit the most grievous errors in this regard. Duval mentions a case of functional vomiting of four years' standing, which had resisted the most active and varied treatment, and for which no less a man than Chomel advised cold affusions from a bucket for five minutes. The patient almost collapsed, and it was difficult a year later for Dr. Monneret to induce him to try hydrotherapy

[1] Read before the New York Academy of Medicine, November 7, 1889.

again. Duval restored him by rain and jet douches of a few seconds' duration in six months.

Hysteria in its protean forms presents a broad field for hydrotherapy. In my personal experience many cases have yielded to tonic influences of various hydriatic procedures. Here, too, it is important to differentiate the types of the malady, and to adapt our procedures to each one with precision. In the sthenic forms, occurring in well developed women, especially among those who are leading a life of luxury and ease, the calming effect of the prolonged wet pack is indicated. Such patients require a daily pack, from one to two hours, in a linen sheet wrung out of water at 75°. The discipline resulting from the enforced rest, the soothing influence upon the peripheral nerves (as Heimar and Krebs have shown by physiological experiment) by the moist vapor which forms between the blanket covered sheet and the closely-enveloped body, the reduction of the pulse (which has also been demonstrated by Johnson and Petri), the withdrawal of blood to the periphery—all these factors determine a condition of the central nervous system which must favor a restoration of the lost equilibrium. And this is really the result. The patient, after the second or third pack, becomes more calm, her excitability is diminished, and if the treatment is aided by other remedies, medicinal and hygienic, it will almost certainly be effectual, according to my limited personal experience. In these cases it is well to be cautious about the temperature and duration of the half bath which should follow all such packs (for the purpose of restoring the tone of the superficial vessels). The temperature should be about 85° F., and a sponge should be used rather than the hand, the patient always assisting.

In the asthenic form of hysteria, in which the patient is hypochondriacal, or in which a paroxysm is brought on by psychical causes, especially if she be anæmic, the rapid application of water at a temperature of 50° to 60° F., is indicated. This may be done by affusions while the patient stands in hot water, or by a plunge into water of 60° to 65° F. If a douche is convenient, water at 40° to 45° may be used for two or three seconds. The aim here is to stimulate the peripheral nerves, and through the latter the central nervous system. At the same time we obtain by these measures the general tonic effect upon the health and nutrition. The Scotch douche, which is an alternating stream of cold and warm water, is useful in melancholic patients, whose general tone should, however, be elevated by other hydriatic procedures and medicinal agents. "The treatment of hysteria," says Fleury, "is certainly one of the most beautiful triumphs of rational hydrotherapy." The eminent clinician, Becquerel, writes: "During three years I have treated all cases of hysteria, hospital and private, by hydrotherapy, and I may say with assurance that every case yielded; the treatment, however, requires three to six months. Hydrotherapy replaces all other remedies."

In the Montefiore Home we have discharged three cases cured which had been admitted because they had been pronounced incurable.

In *chorea* I regard the treatment incomplete if the application of cold water in some form is omitted. During the past year I have completely restored two little girls who had been treated in vain by medication alone, by daily ablution with water at 65° F. and large doses of Fowler's solution.

From the time of Preissnitz, who, under the eyes of reliable medical observers (one of whom, Schedel, reports the case) restored a young English lady, aged sixteen years, suffering from chorea of two years' standing, which had resisted all medicinal treatment, hydrotherapy has again and again been successfully invoked. We require here the impact of very cold water by the douche, which should, however, be gradually attempted by timid patients. Duval regards it as the best treatment of chorea; he applies the cold douche to the spine and to the most agitated parts, followed by active friction.

In various forms of neuralgia hydrotherapy has afforded many triumphs. In my own personal experience sciatica has yielded more readily than other forms. In the acute form the patient is wrapped in a dry woollen blanket; pieces of old woollen blanket two and four feet, doubled, are thoroughly wrung out of boiling water by means of a wringer. These are, after lifting the blanket, closely applied to the affected limb over the region of the nerve, are rapidly changed until the parts become thoroughly congested and the patient is bathed in perspiration. This treatment continues about half an hour and is equivalent to a Turkish bath. The blanket is now removed successively from various parts of the body, beginning with the affected limb, and these are rapidly washed with water at 65° F. and dried. By this treatment I have succeeded in overcoming some of the most unyielding cases of sciatica, acute and chronic.

In *chronic* cases in which the general health is depreciated, the general tonic treatment by cold ablution, douches, or plunges is indicated. Duval, to whose magnificent book on practical and clinical hydrotherapy, published last year by Bailliere, I shall have occasion to refer frequently, applies the cold douche or rain bath, sometimes preceded by the sweat bath. From his large number he details six remarkable cures, giving, as he always does, the full histories, containing the names of the physicians who sent him the cases. His treatment will be made clear by the following abbreviated history: Patient sent by Sir Andrew Clark of London, on the 16th May, 1867, a lady, thirty-four years old, was attacked by lumbago in January. Pains passed down into the legs and thighs. After various methods of treatment, including blisters, our honorable confrere decided to appeal to hydrotherapy. When I saw her, the leg was flexed upon the thigh; she had to be carried to the *salle de douche*. She first received an ablution with water at 24° (75.2° F.). On the next day the same at 18° (64.4 F.), followed immediately by a sprinkling douche of two minutes passed over the entire body, especially the left leg, with water at 11° (51.8° F.). On the next day a rain douche of one and one-half minute, followed by a jet upon the most painful points with water at 11° (51.8° F.). This was continued until the 21st without sensible improvement.

On the 28th a hot-air bath preceded the douches.

On the next day she pronounced herself improved. Under this treatment she convalesced and was discharged cured on the 28th July.

In all types of *chronic neuralgias*, unless they be of organic origin, the therapeutic resources have not been exhausted until a thorough course of hydrotherapy has been adopted. Those cases especially which have proved unamenable to ordinary medicinal treatment, should be subjected to the best hydriatic method adapted to them. As many of these cases are connected with anæmia and chlorosis, the treatment addressed to these complications frequently restores the patient's health.

If there be one condition in which the tonic effects of hydrotherapy are pronounced, I may say that condition is functional anæmia. The mode of action in this malady, has been referred to at length in the able work of Putnam Jacobi, and its practical utility has been demonstrated by incontestable clinical evidence. For many years I have been in the habit of prescribing cold ablutions when the patient is still warm from bed, as a prominent element in the treatment. This simplification of the method adopted by special hydrotherapeutists, like Fleing, Winternitz and Duval, has served me so well that I must insist upon its value. I might give you numerous observations on the subject, cases in which all the most valued medicinal and hygienic measures have failed, until this simple auxiliary was added, and changed the entire aspect of the case. Even in poor servant girls, in whom anæmia and chlorosis are so common, who are sometimes brought to us by their sympathetic mistresses, with ashen faces, cardiac bruits, glassy eyes, &c,, an astonishing change has been made by simply adding cold ablutions to the iron or other treatment. It will not suffice, however, to tell an anæmic patient, "you must bathe in cold water." The importance of the shock from the brief impact of cold water must be impressed upon them, and the physician should prescribe the temperature of the water. In the early summer months when the water is 70 to 75° F. and the air not much warmer, the shock will be slight. Ice must be added to a basinful of water, or several basinfuls should be precipitated over the shoulders and body from a height, in order to compensate by the mechanical effect for the absence of temperature difference.

In winter my usual prescription is to stand in sufficient warm water to cover the feet, and after turning the cold water on, to catch it up with the hands, or with a small pan, and dash it over successive parts of the body. Rapid drying and friction must follow. After the patient becomes accustomed to the cold water, I advise the plunge into a tub three-fourths full of water not less than 55° and not more than 65° F. Its duration must not be longer than is required to wet the entire body. This simple substitute which, like others mentioned, I have introduced to replace the more complicated hydriatic procedures found in special institutions, will avail in a large proportion of cases. The more obstinate must be subjected to the skilled applications of hydrotherapy. An illustration of the latter method is furnished in the following abbreviated history by Duval. Mr. C. De Limon sent us on the 17th of October, 1876, Mr. X., age twenty-one years. Addicted to a sedentary life and from other causes he became very feeble, with difficult digestion. After having tried iron, tonic wine, exercise, etc., unsuccessfully Dr. Limon recommend a hydrotherapeutic course. The latter was begun by a rain douche of ten seconds, with water at 48° F. (9° C.) followed by dry friction. In the evening same treatment—with cold food and water as drink. No change of treatment was made for a month. He was now a little better. The douches were prolonged to twenty seconds, and we added a jet douche of half a minute upon the whole body, finishing upon the feet. On the 25th amelioration was marked; the head became clear, the appetite improved, the strength returned, and also his vivacity.

The treatment was continued until the 11th of January, 1877, when he left us, entirely transformed and happy to live. We have seen him since that time quite well. Duval cites twelve histories, selected from a large number, in which he details similiar treatment, varied, however, according to the type of anæmia and condition of the patient. In the physiological portion of my paper I have referred to the scientific accuracy with which the improvement in the blood has been demonstrated. Winternitz, too, has in numerous cases of chlorosis and anæmia proven with Fleish's Hæmatometer, that the oxyhæmoglobin of the blood was rapidly and considerably increased by proper hydriatic procedures. When anæmia is dependent upon the cachexia of organic disease, nothing permanent can be accomplished, of course. No one recognizes this fact more than the scientific hydrotherapist. The fact remains positively demonstrated, however, that from the average of cases submitted to the treatment, a large proportion gain in weight, and improve in general condition.

Winternitz has carefully recorded the weight of 2,400 patients of all kinds at his private institute in Kaltentengeben, of whom 56 per cent. gained weight. This is the result of improved appetite and digestion; hence increase of food consumption; hence a progressive metamorphosis. In order to obtain this effect the rule should be: first, not to apply a more powerful thermic or mechanical nerve excitation than the respective organism is capable of bearing without excessive reaction, and second, to so graduate the heat abstraction, that the weakened organism may restore it promptly and without excessive exertion.

For this reason it is important to accumulate heat by dry or wet packs, or by previous warming in bed, or by exercise, or a glass of hot milk, tea, or toddy a few minutes prior to the application of the cold water. These will aid in bringing on reaction and preventing loss of heat in delicate persons. The reactive effect should be watched in the improvement of the pulse and its increase; a rosy hue of the skin, and general invigoration, it should not fatigue very much. For this purpose I have found the dripping sheet very valuable. A skilled attendant dips a linen sheet into water at 65° F., and wraps it snugly over the patient's body, while the latter stands in warm water. The arms are not covered. By brisk rubbing with the flat hand on the outside of the sheet, in

which the patient assists, the peripheral vessels are dilated and reaction is more rapidly induced when the patient is rubbed down with a dry sheet afterwards. This is the method I have adopted in the Montefiore Home with satisfactory results, as will be seen.

While on the subject of anæmia, I desire to refer to the fact that in diathetic diseases, as gout and rheumatism, in which the anæmia is a manifestation of defective nutrition, marvels of restoration, as Prof. Semmola justly says, may be accomplished by the skilful adaptation of cold water to the case.

This subject is too broad to be here entered into as fully as I should wish. Suffice it that clinical data from reliable sources are my warrant for this strong statement. Ziemssen tells us, after describing the wet sheet procedure in the prevention and treatment of tuberculosis, "the great advantage of this rubbing down which may be made in loco, without expense, and whose good service may be employed for months and years, is of extraordinary significance in daily practice, especially among the poor."

47 E. 60TH STREET, NEW YORK.

The Polyclinic.

PHILADELPHIA HOSPITAL.

HÆMOPHILIA.

THIS colored woman is now convalescent from puerperal convulsions. She gave birth to a healthy child, but there is now no evidence of septic infection. She had a hemorrhage from the gums and the mucous membrane of the mouth and nose, which lasted for four days. At first I suspected mercurialism, for she had been given calomel in gr. xv doses, with sodium bicarb. It was, in all probability, not due to the calomel, for when it is given in kidney trouble, it rarely, if ever, salivates. Examination of the pharynx and mouth showed no special change, and even though she bled four days, she was not specially weak. She was fed on milk and given stimulants, and soon made a speedy recovery. Examination of the blood showed white corpuscles in abundance, much fibrin and a normal amount of red cells. She had no anæmia, so we were forced to say that she was suffering from leucæmia. Pernicious anæmia in pregnant women is rare and usually fatal. This woman has no malarial history, nor any specific trouble. She is possibly a bleeder or sufferer from hæmophilia. This trouble is transmitted only by the mother to her children, and not by the father. It is not always fatal, and progressive attenuation of the virus causes it to disappear if good hygienic rules are observed.

I recall the case of a woman, aged twenty-five, with an antecedent history of hæmophilia, who came into the hospital with symptoms of abortion. Shortly after admission she had a hemorrhage from the womb, vagina, stomach and mouth. I tamponed with iodoform, styptics and injections, but without effect. She was given good nourishing food, and in a few days completely recovered. In the case of the woman before us we can find no cause for the hemorrhage, unless it be due to some bad teeth in the mouth. We can find no history of hæmophilia in her family.

But after calling it leucæmia, or hæmophilia, what can be done by way of treatment? She has been given those things that improve the blood, such as iron and arsenic—the latter affording better results than the former—administered in repeated doses, as often as the stomach would bear it. Digitalis was given to strengthen the heart. When she could not take fluid into her stomach, we injected sterilized water into the intermuscular spaces. We thrust the hypodermic needle deeply in and allow several ounces, representing a one per cent. solution of sodium chloride, to escape into the connective tissue and then close the aperture with collodion. This increases the volume of blood, establishes equilibrium, and makes the pulse strong. This may be used to advantage in surgical hemorrhage and shock. Three ounces will be absorbed in one half hour. These injections are used in pneumonia in this hospital, and I have yet to learn of a single abscess when the needle was deeply inserted. For the stoppage of the hemorrhage we used tannic and gallic acid, tincture of myrrh, iron and turpentine, but without avail. Her child exhibited a complication in its history, for it bled at the umbilical cord, and the only way this could be checked was by passing two hare-lip pins under the bleeding spots, and applying a firm ligature.

I recall another case of an anæmic woman who complained of pain in her stomach, with disordered menstruation. She was given a placebo, and the next morning her nose began to bleed, but none of the ordinary methods of treatment stopped it. The nares were plugged with gauze dipped in tannic and gallic acid, and iron was given, but she died in three or four hours. It seemed that the bleeding continued from the posterior nares, that she swallowed the blood, and thus it escaped notice until it was too late.

As to the prognosis in this case, it is favorable; but she is liable to interstitial nephritis with eclampsia. Arterio-sclerosis and confirmed nephritis may result. If she is not exposed to mental strain or cold, her trouble may not return. She ought to be under an intelligent physician's care for the next five years, and, as a second child might predispose to subsequent trouble of a similar kind, it would be well to prevent another conception. Typhoid fever may and often does complicate pregnancy, and is liable to be mistaken for puerperal septicæmia. In the case of a woman who was taken with typhoid shortly after the birth of her child, she made an incomplete recovery. The child was weaned at once. The treatment was symptomatic. She was well fed and nourished. Lead was given for the excessive watery stools, with opium; sponge baths and antipyrin for the fever, and milk and alcohol as a stimulant. You may reëstablish lactation by the application of a Faradic current, and the use of good diet. Apply one pole at the breast and the other at the spine.—*Davis.*

The Russian influenza is beginning to show itself on this side of the Atlantic, if we may trust the newspaper accounts. It is most likely that the cases noted are ordinary, non-epidemic catarrhs.

THE REMEDY FOR THE MYCOTIC SUMMER DIARRHŒA OF INFANTS.

IN our issue of the 30th ult. we refered to this subject with a view of presenting to our readers the latest opinions of leading authorities. If the chief etiological element is to be sought in the bacteria, which abound in cows' milk, as recent investigations have clearly demonstrated, the remedy is simple, as it proved to be in the matter of puerperal infection (as was brought out in a recent discussion in New York City). In the case of puerperal diseases Semmelweiss astounded the medical world by reducing the enormous mortality from this scourge to about seven per cent. by simply insisting upon cleanliness and disinfection of the hands and instruments which approached the puerpera. Marvellous as were the results achieved by this common sense practice (adopted after the fertile theories of the ablest men had failed to discover any positive etiological factor) still greater advances were made by those who succeeded Semmelweiss and had the advantage of the bacteriological discoveries of later times. The outcome is, that to-day puerperal infectious diseases are practically abolished by that most simple measure, "strict uncompromising asepsis of the utero-vaginal canal and vulva.

It may be justly claimed, as was done by one of the speakers at the recent meeting of the Pædiatric Section of the New York Academy of Medicine, that Soxhlet stands in the position of Semmelweiss, in this question of infantile summer diarrhœa. By an ingenious method of purifying the milk and preserving it until it reaches the infant's lips, he has succeeded in diminishing greatly the enormous infant mortality of summer. But we should go farther than Soxhlet. If, as is now coming to be recognized as an axiom, sterilization of milk is the *sine qua non* in this question, we must as soon as possible abandon Soxhlet's apparatus, *because it does not sterilize the milk.* We say this on the authority of Pasteur, Loeffler and Lister, who have shown that after milk has been boiled ten or twenty minutes, it is still capable of developing bacilli and spores, which precipitate casein under alkaline reaction. The latter observation demonstrates that the fact, that milk from Soxhlet's apparatus does not readily turn sour, is not a proof that it is sterilized.

That this is really true was proven by the statement of Dr. Caille (to whom we owe the introduction of the apparatus in this country) that Soxhlet does not claim that he sterilizes the milk.

Just here comes our difficulty. Everybody regards the milk sterilized, and we are too prone to rest content under this impression, which is now happily shown to be incorrect by the most enthusiastic advocate and introducer of the Soxhlet apparatus.

Just as Semmelweiss' method proved wonderfully effective in limiting puerperal diseases, so will and does Soxhlet's method aid us greatly in the prevention of summer diarrhœas of infants. While we would therefore not take one jot or tittle from the merit of this benefactor of infants, we are sure he will be the first to aid in bringing about the adoption of a more perfect method, if such can be found. That there is such a method, we have no doubt. It remains for some practical mind to devise an apparatus by which the milk can be held for half an hour at 266° F., and we have the opinion of Pasteur, Loeffler, Lister, Hueffe and other well-known bacteriologists, that such milk will be thoroughly sterilized.

The preparation of milk thus strongly sterilized, in large quantities, its supervision by health boards and experts in bacteriology, its sale at a reasonable price in properly-secured bottles, will do more to diminish infant mortality than all the benevolent and well-meant planning and erection of seaside hospitals, and organizing of excursions for sick babies during the heated term.

At the meeting of the Pædriatic Section referred to above, a sample bottle of Jersey milk sterilized by Soxhlet's method was shown, the price of which was $3.00 (with a rebate of sixty cents for the returned bottles) per dozen bottles of six ounces. This is at the rate of $1.06 per quart. We cite the fact as an illustration of the "infantile" stage of this industry.

THE STAFF AT BLOCKLEY.

THE prospect of a change in the personnel of the City Hospital Staff, has re-awakened the contention of last summer, and in the same objectionable form. These staff appointments, as is well known to most of our readers, have no emoluments connected with them, and are valued chiefly because the holder has the opportunity to study the great mass of clinical material in the hospital, and present it to the students of the city colleges at the clinics. It is obvious that were these opportunities to be confined to one college alone, the Blockley clinics would become a powerful agent in attracting the students of the other institutions away to the one whose teachers were introduced to them under such favorable auspices.

This and the fact that none of the medical colleges is a municipal institution, and hence neither has any official claim in the matter, form the basis of the demand for equal representation on this staff.

The claim has, however, been that the colleges are not to be considered at all, but that members are chosen solely with a view to their efficiency. But the query naturally presents itself, Who is to judge of the relative merits of the candidates? Under the alleged "civil service rules" of Dr. White, the decision rested with the staff, in which the majority of University men enabled them to control the situation absolutely. Whether these men are capable of giving an impartial verdict may fairly be judged by their record. Last summer their action was prompted by the impulse, engendered by Dr. White's cunningly-worded letter, to assert their independence, which they believed to be threatened by the Mayor. Independence is a noble motive from which to act; but it is not exactly the same thing as doing one's duty with impartial justice, and an eye only to the public interests. Later, when the less reputable members of the University party endeavored to excuse this action by inventing another reason therefor, and attributed the adverse vote of one candidate to personal reasons, there was not independence enough in the whole staff for one member to lift up his voice in behalf of the man who was being slandered. Instead of that they allowed the assertion to go uncontradicted, that the Mayor was seeking to force upon the staff a man who failed to pass the civil service examination! So industriously were the words "civil service" bandied about that scarcely any one now knows that there was not the ghost of an examination, or any method whatever, employed to ascertain the fitness of candidates for the staff.

The fact that an examination had just been held for Resident Physician in Blockley, helped to confirm this impression in the minds of the general public, who seldom read carefully. For the independence which bristles up at a fancied encroachment upon prerogative, and will yet refrain from speaking a word in justice to an opponent, we have the heartiest contempt.

At present the question is whether the entire staff shall be re-appointed in a body, or whether some changes shall be made. Dr. White has certainly been an efficient officer on the staff. He has won a reputation as a surgeon and as a man of executive ability. But it is unjust to his colleagues to attribute to him the whole credit of the good work of Blockley's surgeons. They have deserved quite as much commendation as he; and the outcry in the *Telegraph*, presumably inspired by Dr. White, if not coming directly from his pen, is really intended to force one of them to make room for Laplace, and leave White still in his place. With his father at the head of the Bureau, and in perfect harmony with him, it would have been indeed strange if Dr. White had failed to carry out his reforms; while other and equally able men had no such opportunities. In the *Telegraph* editorials, however, he omitted to mention that Dr. White's overbearing manners, and his poor delivery, render him less desirable as a member of the staff. It is in further proof that to him has been attributed credit really due to others, that no evidence of his executive ability is to be seen in the University Hospital, whose mismanagement has been so notorious that the authorities have been compelled to bring Dr. Billings here to restore order.

Professor Ernest Laplace, whose name has been mentioned, is perhaps better known in Europe than he is here. He is one of the very few American surgeons whose professional work has won the respect and approbation of the highest authorities abroad. With men like Koch, in the very fore-front of medical progress, the abilities of this young American have been fully recognized; and there is not a surgeon who practises antisepsis to day, but is indebted to Laplace for the efficiency of his applications. If the Philadelphia profession are not acquainted with Dr. Laplace and his work, the Philadelphia profession would do well to go home and read up a bit.

Dr. Laplace came here from New Orleans last fall, to fill the chair of Pathology in the Medico-Chirurgical College; a position for which no man in America is better qualified. With a comparatively uninteresting subject he has succeeded so well, that students of classes not required to attend his lectures, have been going without their dinners in order to hear him. The readers of the TIMES AND REGISTER have already been favored with articles from his pen; while his work in the wards as a surgeon, has shown his practical ability to be fully on a par with his brilliant qualifications as a writer and teacher. Should the city secure his services as a surgeon to the Blockley hospital, both patients and students are to be congratulated.

Annotations.

OLIVE oil for gallstones is favorably spoken of by Dr. Rosenberg, who cites three cases in which he gave from three to five ounces of olive oil in two portions combined as follows: Ol. olivæ, 200 gr.; menthol, 0.5; cognac, 20; and white of eggs, m. 2 (well rubbed up). In discussing the paper Virchow referred to his experiments, which demonstrated that in fishes, birds and mammalia large masses of fat are excreted and again absorbed by the epithelium of the gall ducts and gall bladder, so as to render the surface of these parts quite white. He concludes that there is a kind of intermediary tissue change, that part of the fat reaches the liver, is excreted from it and passes into the gall passages, a portion reaches the intestine. It may therefore be supposed that in the cases reported, the oil flowed to a certain extent through the liver, passed into it in considerable quantities and then produced the mixture in the gall ducts and gall bladder, which Rosenberg described as the effect of his treatment.

Prof. Ewald had looked up the literature of the subject and found in some cases the supposed gallstones were simply soda soaps; but in fifteen cases whole stones with facets were passed and in two cases, in which large doses of olive oil had been given for intense pains, prompt relief followed, with passage of stones. Ewald's personal experience in two cases was negative.—*Deut. Med. Zeitung.*

Letters to the Editor.

INQUIRY.

I AM attending a child (male), thirteen months old. He has had crying spells since he was born. I treated him with Dewees' carminative, paregoric, and Dover's powder. The child grows, and does not seem to be sickly. It, however, gets these crying spells now, and is at times restless day and night. It does not seem to have any trouble in passing its water, nor during defecation. It sits and plays, but at once drops all and cries, and it must be taken up and carried about. Mother says that at night it cried at times as if a pin were pricking it. The ears do not discharge, nor is there swelling in the meatus auditorius. I had to resort to morphine to produce sleep. Then I prescribed chloral hyd., potas. bromide and morph. sulph. These answered the purpose for a while, but then lost their effect. I am inclined to the opinion that the child has pain in the head, either neuralgia or of some other nature. I have given it potas. iodid., gr. ij, three times a day. Am now giving the elix. phosph. lime, soda, potash and iron (chemical food), three times a day, and at night quinine sulph., gr. 1½ to 2, morph. sulph., gr. ¼. Sometimes one is enough, and at times two or three doses are necessary to quiet the child. The child born previous to this also had crying spells, and required large doses of Dewees' carminative, but at the end of nine months old it needed no medicine. I had given it sulphonal-bayer, gr. xv. The first night this seemed to have a good effect, but after then it failed. The child is bottle-fed, and also eats at the table. It has cut six or eight teeth.

What can be the cause? How can I stop the crying and the morphine?

The child's "crying spells" are quite probably due to an obstinate form of colic. You state that the babe "does not seem to have any trouble in passing its water, nor during defecation." The diagnosis is based upon the following features: the paroxysmal character of the attacks, the restlessness, and the fact that the "child is bottle-fed, and also eats at the table." The number of stools in the twenty-four hours are not mentioned, but it must be born in mind that one passage daily in a child thirteen months of age, is to be regarded as constipation, which, we suspect, is present in this case. In some of these cases intercurrent attacks of diarrhœa are observed, more particularly where the food given is unsuited to the digestive powers of the infant.

Your first care should be to regulate the diet properly, adapting it to the digestive power of the patient, and not to his age. Give complete relief to the bowels daily by the use of the inf. senna, combined with tr. belladonna. To control the severe attacks of colic, flannels wrung out of hot water and applied to the abdomen are serviceable; also copious injections of warm water and soap.

Instead of the large doses of morphine, the following mixture should be given a trial, administering a teaspoonful every two or three hours during the attacks:

℞.—Sp. ammon. aromat.....ℳ xlviii.
Sp. chloroformi.....ℳ xxx.
Sp. menth. piperitæ..... ʒ ss.
Glycerini ....ʒ iij.
Aq. carui.....q. s. ad ʒ ij.
M.—Ft. tincturæ.

—J. M. A.

Society Notes.

McDOWELL MEDICAL SOCIETY.

Twenty-ninth Semi-annual Meeting, held at Henderson, Kentucky, November 11, 1889.

Morning Session.

THE Society was called to order at 10 A.M. by the President, Dr. John E. Pendleton, of Hartford, Ky.

Dr. Ap Morgan Vance, of Louisville, read a paper on

ANTISEPTIC SURGERY,

in which he said the great progress of surgery in the past ten years has been just in proportion to the increased understanding and confidence in the power of antiseptic and aseptic methods of wound treatment. The day is not far distant when a man will be ashamed to admit the formation of pus in a wound of his making. He is now ashamed of such a result, as he knows that it is by some neglect on his part that it is there. The technique, he said, is to be acquired by reading the medical journals of the day, and making trials of the methods there described.

Dr. Vance then by a series of *dont's* directed the attention of the members to the importance of the little things in this kind of work, reporting cases illustrative of the results to be obtained.

Don't fail, when possible, to have a general bath before doing a major operation.

Don't do any operation with suspicious hands; hot water, soap, nail brush, and penknife should be carefully used by the principal and assistants before any operation. It is best to cut the nails very short so there will be no place for germs to lodge.

Don't just before or during an operation put your fingers about your nose, eyes, or ears, or use your handkerchief, or shake hands with any one. It is better to offend a visitor than to run the risks of infection.

Don't pick up, or allow your assistants to touch, any instrument, sponge or suture that has fallen upon the floor during the operation.

Don't bite off the end of a suture that it may the more readily be threaded.

Don't put your knife, or other instrument, in your mouth, or behind your ear, preparatory to its use.

Don't fail to detail some one to wipe your face during a long and laborious operation.

Don't cough or sneeze over the operative field; consequently the use of tobacco or the presence of a cuspidor should be forbidden in the operating room.

Don't fail, when possible, to have the patient

bathed, and clothing changed, before an operation. When this is not possible, thoroughly cleanse the field, and never make or dress a wound where the surrounding parts have not been shaved thoroughly.

Don't allow any visitor to handle the field of operation, after the patient is prepared, unless he is aseptic.

Don't allow visitors who are doubtful, *i. e.*, who are attending patients with gangrene, erysipelas, or puerperal fever, etc., unless they have taken all precautions.

Don't fail to have the field surrounded by warm sublimated towels.

Discussed by Drs. G. Frank Lydston, of Chicago; A. M. Owen, of Evansville, Ind., I. N. Love, of St. Louis; J. Y. Brown, of Henderson, Ky.; and discussion closed by Dr. Vance.

Dr. I. N. Love made some remarks on the

MANAGEMENT OF FEVERS.

He said nearly all the cases of fever which come under our observation, after it is well established that they are continued fevers, no matter what the cause, the management of them rather than medication is what we wish to obtain, yet there are times when medication is an important part of the management. The latter should be secondary, however. When called to a case of fever we find a high temperature, with a history invariably of chill. In malarial fevers we have a history of days of discomfort, headache, bad digestion, etc., with no well defined chill or rigor. In fever cases the first thing is to clear out the sewers of the patient, keeping open the secretory and excretory organs, by giving good doses of calomel along with compound jalap powder, followed by some saline purgative. Sometimes thorough cleansing of itself overcomes the fever, then proper measures should be taken to prevent its recurrence. The alimentary canal having been cleared out, management rather than medication should be employed.

The ice water given patients should be boiled and kept hermetically sealed in an ice chest; so too with the milk given fever patients. Cleansing the mouth and teeth are important factors. No patient with typhoid fever should have sordes on the teeth. An item of vital importance is tranquillity of both mind and body. Friends should not be permitted to see fever patients. The physician should insist upon the patient using a bed-pan, causing as little muscular effort as possible. With a view to producing this tranquillity the administration of medicines which produce sleep are of great value. Sleep is one of the most curative agents in fevers. In controlling temperature the speaker highly recommends acetanilid. He has used it in a large number of cases with very satisfactory results. Given in doses of 2½ grains, every two to four hours, to an adult, it reduces temperature at least one and a half degree, and keeps it down. The speaker gives it in the form of a solution, with brandy or Tokay wine, which makes an ideal stimulant. He also alternates the sponge bath with the administration of acetanilid.

The hydro therapeutic treatment of fevers had received considerable attention of late, and among the more interesting articles that have been written are those by Drs. Baruch, of New York, and G. C. Smythe, of Indiana.

Quinine, as an antiperiodic, should be ruled out; yet if there is a malarial element it is the remedy to determine it. Quinine disturbs the nervous system, demoralizes the alimentary canal, and impairs digestion and nutrition.

Dr. Love, in closing, favored the pre-digestion of all foods for fever patients for various and obvious reasons, which he gave at considerable length. Bovinine, which is simply an extract of meat: is very satisfactory in such cases, as it is well received, well retained, and is unquestionably very nourishing.

Discussed by Drs. P. Thompson, of Henderson, Ky.; W. C. Cook, of Henderson, Ky.; W. C. Smith, of Henderson, Ky.; G. Frank Lydston, of Chicago; A. M. Owen, of Evansville, Ind.; Brandford Lewis, of St. Louis, Mo., and discussion closed by Dr. Love.

Dr. J. E. Pendleton, of Hartford, Kentucky, read a papar on

TREPHINING, WITH REPORTS OF CASES.

He said trephining within itself is not a dangerous operation. There has not been a record of cases in which all other factors of danger have been eliminated. The operation is done for the relief of some injury or other pathological condition which either impairs the health or imperils the life of the patient.

Operations done for the relief of epilepsy are more nearly fair examples from which to calculate the mortality rate than any other class of cases that have been recorded. Even in these, if the epileptic seizures be due to old traumatisms of the skull, with spiculæ of bones or exostoses impinging upon the brain or its membranes, they should be excluded. It has not been the speaker's fortune to be called to use the trephine for tumors or epilepsy. His experience with the instrument has been for the most part confined to recent traumatic injuries of the head. In two of the cases he had treated exostosis of the inner table was found. He reported five cases upon which he had successfully operated, and four in which the indications for trephining were palpable.

He concluded by saying that much as had been learned and published within the last two decades with regard to the functions of the cerebral centers, we are not yet in possession of sufficient knowledge to shield us from the danger of making mistakes in locating cerebral lesions. The very complex anatomical arrangement of the nervous centers, and their conducting tracts; the fact that two or more areas may be intimately connected with the same function, and that lesions of the same location in different individuals may not produce like definite results, conspire to hinder correct diagnosis. Tumors and abscesses imbedded deeply in the brain substance that would inevitably have terminated life, have been extirpated or evacuated, and the patient restored to health. Perilous as may seem these daring ventures in brain surgery, the speaker said there will be found many whose lives have been made so miserable by constantly recurring fits of epilepsy, and failed of relief in other directions, who will gladly avail themselves of almost any operation to get rid of their

malady. In depressed fractures, in sub-dural or sub-cranial hemorrhage, or in traumatic abscess, if the focal symptoms are of a reliable character, there should be no hesitation about operating.

Judging from his own observation and all the information he had gathered concerning the conditions of the skull and brain for which trephining may be done, he could only say that the propriety of operating depends mostly upon our ability to make a correct diagnosis.

Discussed by Drs. Vance, Owen, Lydston, and discussion closed by Dr. Pendleton.

Dr. E. H. Luckett, of Owensboro, Ky., read a brief paper on

THE RELATIONS OF MOTHERS IN NURSING THEIR CHILDREN.

He said in investigating the operation of natural laws we cannot fail to observe the mutual relationship and reactions which they produce in their fulfilment, and this relationship holds good whether they are acting rationally or aberrantly. In no field of their operation is this to be more observed than in the laws regulating biological processes or pathological divergences. Each law, as it applies itself to the development of functional activity in this or that organ, is aided by its relationship. In but few organs is this law more beneficently displayed than in the milk glands and uterus, where the one has for months been caring for and growing a loving being, and the other developing for the care of the infant in its independent existence. To ruthlessly set this order at defiance, is to invite serious disaster to the woman, and greater perils to the child. There is no condition of humanity more to be deplored than that arising from the pathological conditions following childbirth, and among the many causes for these disturbances failure to nurse stands out boldly and forebodingly. That every mother should nurse her child, except from want of milk or grave disease, will not be gainsaid. It is the demand made by the law of her condition, and she cannot shrink the task or transfer the responsibility without inviting injurious results to herself, and taking large chances for physical and mental defects to her child, entailing upon it a puny existence, and too frequently an early death. Nature intended that woman should nurse her children, and consequently that pregnancy and child-bearing should not occur oftener than the normal condition permitted, amounting to one child-bearing period in eighteen months or two years. But with the dry woman this occurred in from ten to fifteen months, subjecting her to all the mental anxieties, all the nerve perturbations, both reflex and direct, and all the functional derangements incident to this period almost continually during the life of her fecundity,

Another condition arising much more frequently in the nursing woman is abortions. This is no doubt to a great extent the result of the frequent pregnancies which women are subject to. These abortions are one of the most fruitful causes of local pelvic troubles, both acute and chronic, and add largely to the list of penalties which women pay for neglect of duty, in discarding the motherly care of their offspring.

Discussed by Drs. Hanna, of Henderson, Ky., Love, Owen, and Lydston.

Dr. Bransford Lewis, of St. Louis, Mo., read a paper on the

TREATMENT OF GONORRHŒA BY THE OINTMENT METHOD,

in which he deprecated the use, in the early stages of gonorrhœa, of astringents, caustics, or other means, antiseptic or otherwise, which would tend in any way to increase the irritation already present, giving as his reason that, aside from the injurious effects which they might produce on that account, they were inefficacious in reaching or killing the gonococci, the morbific agents, because of the behavior of the latter with reference to the tissues in which they dwell. Admitting the inability to cut short a specific gonorrhœa in a few days or a week, he had advised a plan of treatment, having for its object the conduction of the disease through its several stages as quickly, as pleasantly, and as safely as possible. And nothing appeared to be more liable to attain these ends than the introduction of a bland ointment, medicated as desired. It is soothing to the inflamed membrane; it keeps the opposing surfaces from rubbing against one another, and this way obviates all auto-irritation. It affords a continuous application for any medicament, without giving rise to any additional trouble to the physician or annoyance to the patient.

Dr. Lewis then exhibited the instrument or applicator which he uses, and described it in the following language; "This instrument is simply a hard rubber ointment box, fitted at one end with a screw-piston, for pressing the ointment out the other end into the soft rubber catheter attached thereto. The catheter, having three holes at its end, is a No. 2 French, small enough, smooth enough, and flexible enough to glide for a half inch or so into the most sensitive urethra, generally before the patient knows that it is in. The ointment is then squeezed out, pressure being maintained all the while around the glans, so that it is compelled to pass backwards over the inflamed area. The catheter is then withdrawn, and a muslin hood, lined with clean, non-absorbent cotton, is placed over the penis, and retains the application until the next urination."

Lately he had been using albolene, an ointment base which is such an inert and indolent substance that it neither changes nor becomes rancid with keeping, or in combination with medicines. It is odorless, and almost tasteless. He prefers it to lanolin, because of the qualities mentioned, and is now using it exclusively, and with perfect satisfaction.

Discussed at length by Drs. Lydston, Brown, Vance, and closed by essayist.

Dr. William Cheatham, of Louisville, Ky., read a paper entitled

PHLYCTENULAR OR SCROFULOUS OPHTHALMIA.

He said the management of these cases is quite simple in a great majority of them; but we occasionally come across cases where the cornea may be perforated, or one in which we have frequent relapses, which puts the physician to no end of trouble and worry. In these cases the hygienic management and

constitutional treatment is of extreme importance; in fact, the most frequent cause of this affection is bad hygiene. As to feeding, all sweets should be cut off, likewise tea and coffee. Fresh meat should, if possible, be given twice a day—none for supper. Limit the patient to good, nutritious food. Patient should be kept out of doors as much as possible. The local treatment in phlyctenular conjunctivitis is cleanliness, with hot or cold carbolized water, as the patient prefers. Atropia sulph. grs. ij, aqua dest. ℥j, to be dropped into the eye three or four times a day, if the inflammation is severe, or if there is any photophobia. If dry calomel can be dusted into the eye about noon each day, with a camel's hair brush, it should be done; or the calomel may be mixed with pulverized white sugar, half and half.

Discussed at length by DR. J. M. RAY, of Louisville, Ky.

EVENING SESSION.

DR. P. THOMPSON, of Henderson, made some oral remarks on the

HYGIENIC MANAGEMENT OF THE NEW BORN.

DR. G. FRANK LYDSTON, of Chicago, read a paper on the

EVOLUTION OF THE LOCAL VENEREAL DISEASES,

in which he said that following the period of confusion regarding venereal diseases which existed up to the advent of Ricord and his school, came the belief that gonorrhœa was a specific entity, and not identical with syphilis. Bassero, a pupil of Ricord's, taught that chancroid and chancre were each specific entities, and this view is the most generally accepted one at the present day. There have arisen, however, in recent years, a few heretics, who, while assuming that syphilis is a specific entity, hold different views regarding chancroid and gonorrhœa. Personally, he was convinced that chancroid and gonorrhœa are diseases which may arise *de novo*, and which are, in the true sense of the term, not specific. It is only by an acceptance of this theory that it is possible to understand something of the origin of those diseases. It may not be possible to demonstrate the origin of all infectious diseases, but it is incomprehensible that a "specific" poison has always existed in any instance. Through the germ theory we apparently see a little light regarding the origin of infectious diseases. Diseases are incident to the life of every animal, and as we study the evolution of the animal, so should we study the evolution of its diseases. Diseased germs are the natural enemy of man. He has been able to contend successfully with all other adverse elements, but not with those little organisms—the germs of disease.

He believed that the local venereal diseases are the result of the propagation and differentiation of germs primarily innocuous. The innocent germs of the atmosphere may multiply in a favorable environment, and the result of such multiplication finally become, through successive cultures, virulent. Filth, heat, moisture, and protection from air and light, favored such changes. Thus the descendants of innocuous germs may have properties which are noxious, dependent upon the environment in which they are developed. Thus we may have, by a process of evolution, an apparently spontaneous development of diseased germs. In the higher degrees of cultivation the germ would necessarily acquire properties, by virtue of which it would almost invariably produce so-called specific results.

The effects of the germ, even after it enters the tissues of the human being, vary according to (1) its virulency and vitality. (2) The inherent vitality of the individual affected. (3) Idiosyncrasy. (4) Activity of elimination. (5) The condition of the tissues. (6) The number of germs and length of time of exposure.

The experiments of Pasteur on chicken cholera show conclusively what may be done in the way of modifying germs by proper culture. Is it unreasonable to suppose that such cultivation may occur in nature's laboratory? As a consequence of the widespread variation in the circumstances controlling the development of germs in the female vagina, the essayist believes that there may result from different inoculations of essentially the same products of evolution, different degrees of infection. Thus, the disease acquired by exposure to materials may be (*a*) Simple balanitis, balano-posthitis, or venereal vegetations; (*b*) simple urethritis; (*c*) virulent urethritis; (*d*) simple venereal ulcer, indistinguishable from advanced herpes, and (*e*) classical chancroid.

Discussed at length by DR. LEWIS.

The Society then adjourned.

Book Reviews.

A TREATISE ON DISEASES OF THE NOSE AND THROAT: In two volumes. By FRANCKE HUNTINGTON BOSWORTH, A.M., M.D. Volume one: Diseases of the Nose and Naso-Pharynx, with four colored plates and one hundred and eighty-two woodcuts. Pp. 670. New York: William Wood & Co., 1889.

How can anybody pretend to read books nowadays, since the modest monographs which heralded the advent of this specialty have expanded into the two huge volumes of the work before us? In truth, medical works are no longer expected to be read; but, like the atlas or the dictionary, are simply works for reference.

Taken in this sense, they can hardly be too large, as with a perplexing case upon his hands, the modern physician requires something much more comprehensive than the skeleton work he employed as a text-book at college. Of Dr. Bosworth's volume, the first hundred pages are occupied by the general topics relating to the nose, and four hundred by its diseases. The naso-pharynx monopolizes the next one hundred and eighteen pages, and the remainder is taken up with the operations and two indices. Space forbids us to mention the many excellences of this work; but as the critic's duty is rather to point out faults, we will speak of one—a little one, perhaps—but which mars the work in the eyes of those who love perfection in book-making. This is the carelessness in the framing of prescriptions. Some are in Latin, some in English, and some show a mix-

ture of the two—as on page 229. Some have the names written out and others are abbreviated, while the majority are likewise mixed. As long as the pharmacopœia prescribes the termination *ine* for alkaloids, this should be employed. Uniformity is too great a good to be carelessly sacrificed. We are curious to know where the author finds his authority for "coffæ toastæ," on page 116, or for the "sacchari albæ" following it. On page 367 is an error of a more serious nature; where oil of almonds is ordered, without anything to indicate whether the sweet or bitter oil is intended. It is doubtless true that the average physician and pharmacist would be unlikely to use the poisonous oil; but a book for general circulation may fall into the hands of persons in either profession whom it would be unsafe to credit with that much discretion.

One of the most commendable features of the book is its free, independent tone. In general, such works are so little besides the compilation that the author is hidden behind his library. The opinions of Mackenzie, Moldenhauer, and Zuckerkandl are of value, but the reader wants the verdict of the author upon the various modes of treatment mentioned. This Dr. Bosworth gives with the confidence which springs from great experience and good judgment; and this gives to his book a practical value which far outweighs the faults of expression we have mentioned.

Essentials of Pathology and Morbid Anatomy. By C. E. Armand Semple, B.A., M.B., etc., London. Philadelphia: W. B. Saunders.

This little book of one hundred and sixty pages, making the sixth of the Saunders' Compend Series, is, we believe, destined to find a place in the capacious pocket of every medical student.

The author has compiled within these few pages a fund of information which cannot fail to prove of value to those anxious to acquire the essentials of pathology. The illustrations are numerous and in the main creditable. There exists, however, a lack of clearness about some of these pertaining to bacteriology which is due, at least in part, to too great brevity in the descriptions.

The idea of introducing a chapter upon urinary pathology we believe to be a good one, and worthy of imitation.

Pamphlets.

The Therapeutic Significance of the Cervical Follicles, by Simon Baruch, M.D., Gynæcologist to the Northeastern Dispensary, New York. Pp. 31. Reprint from the New York *Medical Journal* for June 27 and July 4, 1885.

A Review of the Cases of Tuberculosis which Terminated in Death in the Fifth Ward of the City of Philadelphia during the year 1888. By L. F. Flick, M.D. Paper read before the Philadelphia County Medical Society, May 22, 1889.

Two Cases of Removal of Uterine Myoma: one, suprapubic hysterectomy; the other, complete hysterectomy. A new method of disposing of the Stump. Microscopical examination of the appendages. Remarks on the Treatment of Uterine Myoma by Electricity. By Mary A. Dixon Jones, M.D., Surgeon to the Woman's Hospital of Brooklyn. Pp. 44. Reprint from the New York *Medical Journal* for August 25 and September 1, 1888.

The Medical Digest.

In the *Medical World* is reported a case of impaction of fæces which was relieved by repeated injections of coal oil, one pint each. Intense jaundice followed, which proved temporary.

Quinsy.—In the early stages of quinsy, chloral hydrate is nearly a specific, three or four grains to the ounce of glycerine being used as a gargle. It is locally antiseptic, astringent and sedative.

—*Medical Record.*

For cold in the head, while in the acute congestive stage, there is no better remedy than gelsemium. One good, large dose, say ten minims of the fluid extract, taken upon retiring at night, will effectually dispose of this troublesome and uncomfortable affection. One dose is usually sufficient.

—*Medical Compend.*

The Smoke of Hyoscyamus Niger in Toothache.—A Russian practitioner recommends the use of hyoscyamus seeds for toothache. His plan is to burn the seeds and to convey the smoke through a little paper tube to the hole in the tooth. He declares that in nearly all cases one application, or at most two, will suffice to cure the toothache.

—*Lancet.*

Rhamnus Catharticus as a Remedy for Toothache (*Nouv. Remed.*).—Gretschinsky has found a decoction of the bark of *Rhamnus catharticus* gives complete cessation of the pain when introduced into a carious cavity on a bit of cotton. He directs ten parts of the bark to be boiled in a quantity of water which, after standing, will leave twenty parts of liquid, to which one part of alcohol is to be added.

—*Ther. Analyst.*

Dr. Imossi, of Gibraltar, has, according to the *Lyon Medical*, been treating warts with internal doses of tincture of iodine. He has tested the efficacy of the treatment in ten cases, all of which resulted favorably. The dose given was ten drops of the tincture in half a glass of water twice a day. Iodine thus used will cause a slight emaciation of the patient, which loss, however, will be regained as soon as the treatment is discontinued.—*Lanphear's Index.*

Toxic Properties of Boric Acid (J. Plant).—Boric acid has always been considered as an antiseptic non-toxic. However, several cases of poisoning are known to have been caused by this acid when employed, more especially in surgery. The author has undertaken a number of experiments for the purpose of studying its effect on the kidneys. He found that four grammes of this acid, introduced under the skin or given internally to a rabbit or to a cat, produced in these animals an acute nephritis. Albumen, blood and hyaline and epithelial cells were observed in the urine. A microscopical examination of the kidneys showed an acute parenchymatous nephritis.

—*Bull. Gén. de Thérapeutique.*

RENNERT (*Memphis Jour. Med. Sci.*) gives a series of sixty-two cases of diphtheria treated by the local application of Laplace's acid sublimate solution; one part sublimate, five of tartaric acid, and one thousand of water. The membrane is thoroughly removed by cotton-wrapped probes saturated with this solution, which is then applied to the denuded surface. This is repeated in one hour, and again in six to twelve, if necessary. After this the ulcer should be touched with the same solution twice a day till healed. He admits that the treatment is not a pleasant one for patients, friends or physician, but requires the greatest energy for its efficient practice.

SULFONAL—THE OTHER SIDE.—Knoblauch concludes an able scientific and practical paper in *Therap. Monatshefte*, November, by asserting that sulfonal possesses no decided preference over chloral and morphine, but many disadvantages. Aside from the intoxication manifestations, the unsteady gait, paresis of extremities, grating of teeth, vertigo, nausea and diarrhœa, there is at times a protracted drowsiness. Often sleep is very slowly induced, and cannot be obtained with positiveness. The effective dose varies considerably in different persons, and at different times in the same person. In individual cases there were symptoms of intoxication before sleep was induced. There is much truth in the dictum of Montyel that sulfonal is not a medicine, but a poison. Knoblauch does not believe that sulfonal will maintain a permanent place in psychiatry.

IODOFORM AS A CURE FOR CHRONIC CYSTITIS.—Ludwig Frey has used this drug principally in chronic inflammation of the bladder. No matter what the exciting cause was, the cure was radical.

The bladder is first washed out with tepid water which has been boiled, after which the iodoform, suspended in the following solution is injected.

℞.—Iodoform . . . . . 50 grammes.
Glycerine . . . . . 40 "
Distilled water . . . . . 10 "
Gum tragacanth . . . . . 0.25 "
One teaspoonful in a pint of tepid water. Mix.

Three injections a day. By the third or fourth injection the amelioration is so great that the patient no longer suffers. —*Gazette de Gynæcologie.*

RINGWORM of the body is generally very amenable to treatment, judging from the numerous domestic remedies which act so successfully. Sometimes, however, an obstinate case is encountered, and recourse is had to the physician. In such cases a rapid cure is desirable, and the application of the following, once daily, for two or three consecutive days, will generally prove successful:

℞.—Hydrarg. bichloridi . . . . . gr. j.
Tinct. benzoin. comp . . . . . ℥ j.
Misce.—Sig. Paint over affected part.

Care should be exercised not to paint too large a surface, as the above mixture is toxic. If an excoriation should exist, it should not be applied, as it is irritating to the wounded integument.

—*Medical Chips.*

GONORRHŒA.—Neisser's treatment is as follows: He begins with four to six daily injections of silver 1-to-4000, or 1-to-2000, which increases the discharge and renders it more purulent. In a few days it diminishes and becomes thinner; the gonococci are diminished and may disappear. Now the number of injections is decreased to two or one a day; they are substituted by boric acid or zinc; but one nitrate of silver injection is continued for several weeks. If the parts are sensitive even a 1-5000 injection may be a useful parasiticide. Sitz and full baths are useful accessories. Only when anti-bacterial remedies fail, are internal medications resorted to. Balsam copaiba alone displayed a good effect upon the gonococci. The anti-bacterial treatment is continued when complications, especially epididymitis, occur, contrary to the usual practice.

—*Wiener Med. Presse.*

THE TREATMENT OF CONSTIPATION IN PATIENTS SUFFERING FROM UTERINE TROUBLES.—Like dyspepsia, the treatment of constipation in these patients presents special indications, which are important to know.

It would seem that after we have given a purgative, and generally the least disagreeable one, that it would only be necessary to continue the same to establish the proper treatment.

Nothing is less reasonable.

In women subject to uterine hemorrhage, or even only abundant menses, the usage of drastic purgatives should be forbidden, as well as of rhubarb.

This last substance should never be used where there is abundant menstruation, nor when hemorrhoids are present.

On the other hand, it is rhubarb which we must choose in lymphatic patients who are gaining in weight and who notice a diminution in their menses.

℞.—Powdered rhubarb . . . . . 10 grammes.
Acetate of potash . . . . . 2 "
Divide in twenty powders.
Take one before each meal, every day, or every other day.

In arthritic persons the following prescription is useful:

℞.—Sulphur, washed and sublimed . . 10 grammes.
Calcined magnesia . . . . . 4 "
Powdered rhubarb . . . . . 4 "
Cream of tartar . . . . . 8 "
In eight powders.
Take from one to three powders at night, three hours after the meal.

In herpetic persons, as in arthritics, sulphur united with iodide of potassium renders great service.

℞.—Iodide of potassium . . . . . 10 grammes.
Sulphur, washed and sublimed . 6 "
One to be taken after each meal.

Mineral waters such as Hunyadi Janos, Pullna, Birmenstorff, Laroche-Guyon, Atunn are also indicated in similar cases.

When a congestive state of the utero-ovarian system is present, we may add frictions of soothing or irritating applications on the lumbar region morning and night. —*L' Union Médicale du Canada.*

TREATMENT OF OZÆNA (Dr. Moure).—The general treatment of ozæna, which is so rebellious to treatment, consists especially in modifying the general condition, and for this purpose we can use the preparations of iodine, arsenic, etc., but a sojourn at the seashore generally gives the best results.

It is more especially the local treatment which engages our attention. This will consist principally in the use of irrigations; these should always be at a temperature of from 20° to 30° (Cent.). They should be abundant.

We commence by using one pint of water containing an alkaline salt (chloride of sodium, bicarbonate of soda, chlorate of potash, twenty grammes to a pint of warmish water). Immediately after this cleansing solution we use an antiseptic irrigation, taking care to vary from time to time the antiseptic employed; the following may be used in the beginning:

℞.—Phenic acid . . . . . 20 grammes.
Glycerine (pure) . . . . . 100 "
Alcohol at 90° . . . . . 50 "
Water . . . . . 350 "

A teaspoonful to half a pint of tepid water.

After the phenic acid has caused the disappearance of the odorous symptoms, which generally takes from one to two weeks, we replace it either by chloral, resorcine, salicylic acid, salicylate of soda, or by creoline. As the last-named drug has the inconvenience of being very caustic, for the reason that it forms an emulsion and not a solution, we should not administer it, excepting in small doses.

℞.—Creoline . . . . . 1 gramme.
Alcohol (pure) . . . . . 120 "

One teaspoonful to a pint of tepid water.

Naphthol gives equally good results, but preferably in a camphorated solution.

Alumina aceto-tartaricum is also used.

℞.—Alum. acet.-tart. . . . . 20 to 40 grammes.
Acid. boric . . . . . 80 to 100 "

One teaspoonful to one-half, or to one, pint of water.

The liquor Van Swieten should not be used, as it is dangerous.

In obstinate cases the treatment should be terminated with pulverizations.

℞.—Acid. phenic . . . . . 2 grammes.
Crys. resorcin . . . . . 3 "
Pure glycerine . . . . . 50 "
Water . . . . . 300 "

After some time we replace this antiseptic liquid by more astringent solutions: tannin, boric acid, alum, or an antiseptic vinegar, and when the mucous membrane is too dry, we use the following solution:

℞.—Salol . . . . . 5 grammes.
Vaseline . . . . . 150 "

Fumigations and humage give equally good results. The following solutions, heated, should be employed (en humage) for one or two minutes after the irrigation.

℞.—Camphor . . . . . 8 grammes.
Tincture of iodine . . . . . 10 "
Iodide of potassium . . . . . 2 "
Tar . . . . . 12 "
Alcohol at 90° . . . . . 100 "
Water . . . . . 250 "

—*La Tribune Médicale.*

Medical News and Miscellany

FOR the cure of hiccough, the *Allgemeine Weiner Medizinische Zeitung* recommends a teaspoonful of pulverized sugar, wet with an equal volume of wine vinegar.

DR. W. H. WALLING is giving a course of lectures upon the principles of electricity, and its practical applications, to the nurses at the Pennyslvania Hospital. The lectures are given on Thursday evenings in the library.

DR. J. C. FOLTZ has been elected Senior Resident of the Germantown Hospital, in place of Dr. Zimmerman, who has been elected Resident Physician of the Orthopædic Hospital, and Dr. Cleveland has been elected Junior Resident.

During November 55 new cases were treated at the Germantown Hospital. In the general dispensary there were 326 new cases, in the eye department 259, and in the ear, nose and throat department 146 cases; 347 prescriptions were given, and 13 ambulance calls made.

AT the regular monthly meeting of the managers of the Episcopal Hospital, Dr. Richard H. Hunter was elected Visiting Surgeon; Drs. B. Reath, Jr., and Elliston I. Morris were elected Visiting Physicians to out-door dispensary, and Dr. Stavely was elected Resident Physician for the term.

DON'T let everybody kiss the baby, says Dora Harvey Vrooman. In the first place many diseases are carried by kissing; and, in the second place, babies have preferences as well as grown people.

But if diseases be so likely to result from kissing, it is strange that such affections are not epidemic.

EGYPTIANS are said to bear surgical operations with extraordinary fortitude and success, shock being almost unknown. In one case a man's thigh was amputated at 2 o'clock, and he was sitting up and lively at 6 o'clock. The reason of this is the resignation inculcated by their religion and their simple diet and pure habits.

A PENNY-IN-THE-SLOT device for giving shocks from an electric battery has brought serious consequences to some of the patrons of this latest form of the popular craze. Nervous prostration, fits, and like disorders, in several cases have given the victims a gratuitous surprise that may serve as a warning to others who are more curious than wise.

LONDON and Paris each report twenty deaths in one week from typhoid fever; while New York and Brooklyn each report eight, one more than Philadelphia. We do not hear that any of these cities are agitated over the matter, that their leading physicians are memorializing the authorities, or that their newspapers are driving off business by exaggerated statements, cartoons, etc. In fact, they pursue the even tenor of their way, and do not appear to think the situation so serious as to call for heroic measures.

WHAT was the language spoken by Christ? This question is being discussed by Rev. M. J. Dennis and Dr. Carl H. Von Klein, in the Dayton *Daily Journal*. We note that our confrére, who maintains that the language was Chaldaic, exhibits a scholarship which is rarely manifested by physicians, though it is very frequently possessed by them.

THE New York *Sun* advises gentlemen not to indulge in cold plunge baths in winter, as it tends to make the face pimply. Tepid baths are recommended as cleansing and refreshing.

This shows how little the *Sun* knows about it. No cosmetic equals cold water, frequently and liberally applied to the whole body.

During November the following cases were treated at and visits made to the Pennsylvania Eye, Ear and Throat Infirmary, at the northeast corner of Thirteenth and Chestnut streets: Eye patients, 207; ear patients, 60; throat patients, 9; total, 276. Visits made by eye patients, 1,295; ear patients, 894: throat patients, 244; total visits, 2,433.

DR. G. F. WILBUR, of Asbury Park, read a paper at the meeting of the New Jersey State Sanitary Association, on the Need of Medical Officers for School Districts. The paper was a good one, and the author gave many good reasons for his position. In fact, the need of physicians on school boards is so obvious that we cannot believe that any one will care to deny it.

A NATURAL Turkish bath has been discovered near Salida, Colorado. In digging a well not far from the Wellsville Hot Springs a cave was struck with apartments similar to the rooms of a house, the heat being so intense as to cause a veritable sweat bath. The largest room was twenty feet long, ten feet wide and ten feet high, and the walls and ceiling perfectly smooth.

THE example set by THE TIMES AND REGISTER has been followed in a number of instances. The *Practitioner*, of Chicago, has swallowed up that lonely orphan, the *Medical Waif*, and the *Analectic* has united with itself *Townsend's.—Epitome.*

We hope the process will continue until we have about one-fourth the number and four times better journals than at present.

THE Faculty of the Jefferson Medical College gave an interesting exhibition of apparatus used in anatomical research at the laboratories of the College. The exhibition was planned and arranged by a commitee appointed by the Faculty, consisting of Professors Chapman, Forbes, and Longstreth. Drs. Coplin and Williams had charge of the departments embracing "Methods of teaching Laboratory Work," and "Microbes of Normal Sections."

The Historical Department was explained by Dr. Vansant. Prof. Longstreth gave a stereoptical exhihition, to demonstrate the manner in which the subjects were placed before the students. The practical use of the instruments displayed was explained by Prof. Chapman.

THE Board of Health of Edgecombe, Me., has discovered in a hovel on the outskirts of the town, an insane woman, who for seven years has lain on a rough floor and without clothing, because her family were too miserly to pay for her care in an insane asylum.

If lunatics were to be treated in an asylum with the neglect and cruelty they receive at the hands of their relatives, what a howl of execration the latter would raise.

CAMDEN possesses a surgical wonder in a man whose forehead has been so crushed that a silver plate under the skin serves the purpose of bone; some of his ribs are gone, and his internal organs are so awry that the heart gets in its work from the right side. He was an engineer and in reversing his engine in case of an accident he was thrown into the machinery. At the time his leg was broken in four places. He now solaces his remaining faculties by morphine indulgence.

M. PASTEUR has addressed a letter to the late Lord Mayor acknowledging, in the name of the Council of the Pasteur Institute and his own, the receipt of the sum of 40,000 francs voted by the Mansion House Committee as a donation to the Pasteur Institute, with an expression of grateful thanks for the valuable donation and the "flattering" reference to the results obtained through the application of his investigations.

SCARLET fever is epidemic in Ithaca, N. Y. In one part of the town where it is particularly troublesome, it has been found that the disease originated in the family of a washerwoman, one of whose children had a slight attack of scarlatina. She kept the fact of the child's illness to herself and continued to take in washing. The result was, as might have been foreseen, a spread of the disease, and several weeks elapsed before the trouble could be traced to its source.

"IT is with the most profound consternation that I have to report these five cases of death, due without any doubt to the treatment employed by me," is the way that an honest writer in one of our foreign exchanges begins his article. It is often more instructive to read of other's errors than of their successes, and it is a praiseworthy undertaking for one to report his mistakes, but not many would have the courage to do so in such a blunt fashion.—*Medical Record.*

STATISTICS OF LEPROSY IN THE UNITED STATES. In view of the general impression that leprosy is spreading in this country, it is desirable, in the interest of the public health, to obtain accurate information upon this point. The undersigned is engaged in collecting statistics of all cases of leprosy in the United Strates, and he would ask members of the profession to aid in this work by sendihg a report of any case or cases under their observation, or coming within their knowledge.

Please give location, age, sex and nationality of the patient, and the form of the disease—tubercular or anæsthetic; also, any facts bearing upon the question of contagion and heredity. Address

DR. PRINCE A. MORROW,
Journal of Cutaneous and Genito-Urinary Diseases.
66 West 40th Street, New York.

In a Russian journal is reported the case of a woman who procured an abortion by taking about twenty-five grammes of gun-powder in a little liquor. Probably the niter was the active agent.

In another case, the same result was obtained by drinking a decoction made from about two tumblerfuls, firmly pressed down, of the outer peel of the onion. Should this bit of information become diffused through the laity, we will have the odor of onions as frequently met with, and as suspicious, as that of iodoform.

The corporators of the Philadelphia Polyclinic and College for Graduates in Medicine have elected the following new corporators: F. Percy Smith, Rachael A. Baeder, John Y. Huber, Mayor Sultzberger, Dr. Howard A. Kelly. C. A. Spreckels, Dr. J. M. Gemmill, W. G. Warden, W. L. Elkins and Charles B. Baeder. The vacancy in the Board of Trustees, caused by Dr. Nancrede being called to Ann Arbor University, was filled by the election of Charles B. Baeder.

Cholera has appeared at Mosul, a city which keeps up an active intercourse with Diarbekir, Aleppo and Damascus. As the Syrian desert intervenes between Mosul and the Syrian cities, and the winter renders the mountains difficult to cross, we are likely to have the epidemic reach Diarbekir, thence going to Trebizonde, whence it will threaten Europe. Besides this, in Persia it still prevails at Hamadan, on the road to Teheran, whence the road to Reshd, on the Caspian, is easy; and in the Russian Turkestan it is raging at Bokhara.

Diphtheria has prevailed in Weatherly, Carbon Co., Pa., since 1887. On a recent inspection by order of the State Board of Health, it was found that the epidemic was due to the want of proper precautions to prevent the spread of the disease. Visits had been freely made among families having sick members; when death occurred, the funerals were largely attended; and in some instances bedding and clothing of the victims were sold and used again without disinfection. A reform has begun and it is hoped the disease will soon disappear.

The students of the Veterinary Department of the University of Pennsylvania yesterday attended lectures for the first time since the resignation of Dr. Rush S. Huidekoper, as professor, several days ago. They returned at his request. On Monday last the students appointed a committee to wait on Provost Pepper and request him to meet them in the amphitheatre of the college. This he did on Monday afternoon, when a series of resolutions was read to him, stating that Professor Huidekoper had spent eight of his best years in the interest of the Veterinary Department of the University, and had brought it to astandard unexcelled by any similar institution in the world, while he had been shamefully treated by the Trustees and officers of the University. The students requested that the Faculty assist them in every way to induce Dr. Huidekoper to return to the department, as it would be impossible to fill his chair this term.

After listening to the reading of the resolutions, Dr. Pepper made an address to the students, in which he censured them for drafting the resolutions, and assured them that the standard of the department would be maintained. He expressed his high opinion of Dr. Huidekoper, and stated that it was only his strenuous efforts that prevented Dr. Huidekoper's resignation taking effect a year ago.

Continuing, Dr. Pepper referred to the fact that the veterinary school had for a long time been in a poor financial condition, but that it had at last reached a solid basis.—*Record.*

To Contributors and Correspondents.

All articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from December 3, 1889, to December 9, 1889.

Leave of absence for one month, to take effect on or about December 18, 1889, is hereby granted Major William D. Wolverton, Surgeon, Fort Douglas, Utah, with permission to apply at Headquarters, Division of the Missouri, for an extension of seven days. Par. 2. S. O. 114, Dept. of the Platte, November 30, 1889.

By direction of the Secretary of War, Captain John De B. W. Gardiner, Assistant-Surgeon, will be relieved from duty at Fort Reno, I. T., upon the arrival at that post of Captain James C. Merrill, Assistant-Surgeon, and will report in person to the commanding officer, Fort Supply, Ind. Ty., for duty at that post. Par. 8, S. O, 299, A. G. O., November 30, 1889.

Leave of absence for fifteen days is hereby granted Captain Walter D. McCaw, Assistant-Surgeon (Fort McPherson, Ga.). Par. 3, S. O. 276, Div'n Atlantic, December 3, 1889.

Ball, R. R., First Lieutenant and Assistant-Surgeon. Relieved from temporary duty at Fort Sill, I. T., and will return to his proper station, Fort Riley, Kans. Headquarters Department of the Missouri, Fort Leavenworth, Kansas, December 12, 1889. Special Order No. 182.

Leave of absence for ten days, to take effect upon being relieved from duty at Fort Niagara, N. Y., is granted Major John D. Hall, Surgeon. Par. 11, S. O. 285, A. G. O., Washington. December 7, 1889.

By direction of the Secretary of War, Captain Edward C. Carter, Assistant-Surgeon, will be relieved from duty at Willet's Point, N. Y., upon the arrival at that station of Major Clarence Ewen, Surgeon, and will then proceed to Fort Walla Walla, Washington, and report in person to the commanding officer of that post for duty, reporting also by letter to the commanding general Department of the Columbia.

Changes in the Medical Corps of the United States Navy for the week ending December 14, 1889.

Ross, J. W., Surgeon. Detached from the Navy Yard, Pensacola, Fla., and placed on waiting orders.

Kite, I. W., Assistant-Surgeon. Detached from Naval Hospital, Philadelphia, Pa., and to Navy Yard, Pensacola, Fla.

Rogers, B. F., Surgeon. Ordered to special duty at Norfolk, Va.

Leach, Philip, Passed Assistant-Surgeon. Ordered to duty at Naval Academy, Annapolis, Md

Clinical Lecture.

INDIGESTION. CHOREA. ENDOCARDITIS.[1]

BY J. M. ANDERS, M.D.,

Professor of Hygiene and Clinical Professor of Diseases of Children in the Medico-Chirurgical College of Philadelphia.

INDIGESTION.

THIS little boy, gentlemen, who, you may remember, came before us two weeks ago, troubled with indigestion, returns to-day feeling better. His father reports, however, that while the complaint has not extended further than was first apparent, yet the diarrhœa has persisted, being most marked at night. The gastric region is no longer so tender on pressure as formerly. In some cases, a lack of nervous force as well as muscular power in the stomach contributes to this derangement of the digestive function; this may be the principal cause of the complaint in our patient, inasmuch as no very marked improvement is manifest. Hence, drugs to tone up the motor power of the stomach and bowels are indicated. We shall order here, tr. nucis vomicæ gtt. ij, combined with tr. gentianæ comp. gtt. xv, and enough syrup of ginger to make ʒj at a dose, to be given before meals. The acid and pepsin are to be continued after meals.

CHOREA.

For the third time, this little girl with chorea appears before you, very much improved; and considering the obstinacy of the affection it is indeed gratifying to notice that but very slight twitching remains, and this under the excitement of the moment. Before the clinic, no choreic movements were at all perceptible. She is taking the Fowler's solution in four-drop doses. The first symptom of the toxic effect of the arsenic was observed a few days ago, when there was some vomiting. However, the same dose shall be continued for a day or two longer. Intervals of the complete absence of twitching motions are becoming more numerous and prolonged, thus pointing to a proximate and favorable termination.

ENDOCARDITIS.

Near the close of last week's clinic, we showed you a case of acute endocarditis in a little boy—dwelling briefly on his condition. As this disease is one which is frequently met with, and which you should be well prepared to meet, we shall devote the remainder of the hour to a further discussion of this important subject.

At the outset it must be remembered that, as this disease is often associated with other maladies, symptoms of the latter may mask those of the former, which we are thus apt to overlook. Prior to considering the pathology of acute endocarditis, let us view briefly the anatomical structure of the endocardium. It consists of a connective tissue base, with some elastic fibrillæ interwoven and covered by a layer of flat or new cells; these latter in turn being covered by endothelial membrane. Now, the parts affected in the inflammatory process are the endocardium and the valves, although the latter chiefly. Pathological changes begin by an infiltration of new-formed cells, through the layer of flattened cells; then, from this embryo-plastic layer, the infiltration involves the fibro-elastic layer in the same manner, the cells being heaped even on the muscular fibers of the heart.

[1] Delivered in the Medico-Chirurgical College of Phila.

These various tissues ultimately swelling and softening, become destroyed as the disease progresses, whilst the new cells push out the endothelial membrane of the endocardium, forming thus the first stage of vegetations common to this affection. Consequent upon the roughening which ensues from this cell proliferation, it follows that there must be considerable friction between the blood and that side of the valve which is opposed to the current. Hence, as you are doubtless aware, we have here a factor favorable to the formation of fibrin; and thus are derived from the blood the fibrinous coagula, which adhere to and enlarge the first-formed vegetations. Where there is the greatest amount of friction, then, we find the most vegetations attached to the endocardium, they being more numerous on the auricular than on the ventricular side of the mitral valve, for instance. The chordæ tendineæ may also become involved and have fibrinous deposits on them.

There are two kinds of acute endocarditis; viz., the simple or exudative, and the ulcerative. The first sometimes pursues the ulcerative form, either from an insufficient supply of nutritious materials from the blood, or, from granular degeneration alone (Charcot) or yet, from the breaking down of vegetations, and the production of multiple abscesses. When the last named are broken off, perchance by the force of the circulation, they are called emboli, and if they become lodged in any of the arteries or capillaries—depending upon their size—we have constituted the pathological condition known as embolism. There are thus two classes of emboli, the large and small. The former may lodge in an iliac or femoral artery, or a large artery supplying the head, when hemiplegia may be produced. Small emboli are often arrested in the capillaries of the spleen, kidney, liver, brain, and in the skin, causing ecchymosis. Therefore, in cases of acute endocarditis, these hemorrhagic infarcts may cause suppuration. Such inflammatory symptoms as thirst and an irregularly high temperature coëxisting, point towards the ulcerative form of endocarditis, which is always a serious condition.

Taking up next the etiology of this disease, we may say that any blood dyscrasia whatsoever may give rise to acute endocarditis: irritating matters, specific poisons, and alterations in the composition of the blood may produce the characteristic symptoms; Bright's disease, the exanthematous and irritative fevers, rheumatism and inherited syphilis, also, figure largely as causative agents. Ulcerative endocarditis is especially apt to occur, as a secondary affection, in the course of septicæmia, pyæmia and diphtheria.

The general symptoms which first appear in simple acute endocarditis are usually palpitation, slight pain, embarrassed breathing, or mild dyspnœa and uneasiness. Enlargement of the veins of the head and neck is often observed in children; and while this was quite marked in the present case at first, it has now almost completely subsided. The boy's face, which has an ashy-gray hue, may in other cases assume lividity and become bathed in a continous perspiration. Delirium may seize the patient, especially if there is considerable fever, which seldom, however, has a temperature ranging above 102° or 103°. The character of the pulse is peculiar—at first full and strong, though not frequent, in a few days becoming small, rapid and feebler; strange as it may seem on a moment's thought, we may have a feeble pulse, with tumultuous action of the heart at the same time. The latter is a special feature of acute endocarditis, and denotes a diminished propelling power, due to the softening of the cardiac muscle. We will not detail to you the physical signs as elicited by the examination of the boy's chest last week, merely stating, by way of recapitulation, what was then ascertained in proper order. It was observed principally that the area of the heart's impulse was somewhat extended; that the contractions were exaggerated; and that there was a mitral systolic murmur, easily distinguishable. Concerning the force of the cardiac impulse in acute endocarditis, it has been noticed that when the pain increases, the contractions become more violent. Again, the heart may beat violently one day, and in a day or two thereafter its intensity may be lessened considerably. Listening over this patient's heart again, we hear a slight sound running up to the first heart sound. The swelling and consequent constriction around the valvular orifice is doubtless accountable for this. But, the systolic murmur is due to thickened and incompetent valves, as well as to the roughening on the endocardium. The narrowing of the auriculo-ventricular aperture, in addition to the mitral insufficiency, seems to be especially marked in children when the acute symptoms commence to wear off. It is said that in 50 per cent. of these cases a murmur is audible over the tricuspid valve; none can be detected here, although just above, in the region of the pulmonary artery, a slight scratching noise can be heard by listening attentively.

In uncomplicated cases of acute endocarditis, the prognosis is favorable as regards life. But, as the acute trouble may become chronic, an opinion should be always guarded. The symptoms of ulcerative endocarditis may be simulated by those of malarial infection; and when jaundice, fever followed by a chill, albuminuria or tenderness over the spleen are present, the prognosis is particularly grave. Perforation, rupture or even laceration of the valvular cusps would cause the most distressing symptoms—dyspnœa, a very high temperature, followed speedily by a typhoid state. The course of treatment to be pursued in acute endocarditis will depend greatly upon the coëxisting disease—rheumatism, for example, in which, since the blood is presumed to be acid, alkalies would be positively indicated. That the blood becomes alkaline may be determined readily by testing the reaction of the urine, which in these cases also becomes alkaline after persistent treatment in this manner. It is recommended that opium be not given so freely in endocarditis as in pericarditis. In sustaining the system and toning the bodily economy, concentrated nourishment and the exhibition of the vegetable salts of iron, are, indeed, essential. The temperature of the patient's room should be not less than 70° Fahr. The breast should be well covered with flannel; and unless absolutely necessary, should not be removed for the purpose of making repeated examinations.

Original Articles.

RENAL DISEASE OF SCARLATINA.

By W. M. WELCH, M.D.,
Physician to the Hospital for Infectious Diseases, of Philadelphia.

OF the various complications and sequelæ of scarlatina, there are perhaps none of more common occurrence—certainly none of greater importance—than the kidney affections. In studying these diseases I find it convenient to follow Friedlaender's division of them, which is as follows:

1. The initial or febrile albuminuria.
2. Changes in the kidneys of a septic character.
3. Post-scarlatinal nephritis.

Opportunities for examining the kidneys *post mortem* in the first form of the disease, or during the initial albuminuria, are not very numerous. Death, however, does sometimes occur at this stage of scarlet fever, either from accident or some concurrent disease, and in such cases the kidneys show but little anatomical changes—only such, perhaps, as are due to changes in the nutrition of the epithelium. The microscope reveals simply congested capillaries, and slight extravasations of leucocytes around them, coagulated albumen in the tubules, and an increase of the nuclear elements in the glomeruli. In the very malignant cases there is, of course, more evidence of disease—though even here, as a rule, no gross structural changes exist.

The cause of the initial albuminuria is generally thought to be some changed pressure in the capillaries of the kidneys incident to the febrile state. It is therefore spoken of as simply febrile albuminuria, and is believed by many to have only the same significance as when it occurs in typhoid fever, pneumonia, and other febrile affections. But as it is much more frequently met with in scarlatina than in other febrile diseases, I think it not improbable that it may be consequent upon some direct action of the scarlatinous poison on the kidneys.

This form of albuminuria makes its appearance during the first few days of the disease. It is much more likely to be seen when the temperature runs high—say from 103° to 105° F.—although it is not impossible for it to appear when the temperature runs lower. It usually disappears in a few days; but it may continue longer, and even assume an aggravated form during the decline of the disease. In malignant and rapidly fatal cases it is generally though not invariably present. Bloody or smoky urine is not seen at this early stage of scarlatina, except, perhaps, in rare instances, or very malignant cases.

In regard to the second form of renal disease, or that which results from changes in the kidneys of a septic character, the pathological conditions are more apparent. However, among the patients who die at an early period of this septic process, the pathological changes in the kidneys may not be markedly different from those seen in cases of initial albuminuria; but among those dying later—say as late as the second or third week of scarlatina—the kidneys are often large, flabby, and generally pale, though they may be mottled by injected capillary vessels, and sometimes by foci of extravasated blood. The pyramids show the same injected appearance, and, at their base, minute abscesses or cheesy spots are sometimes seen. When examined under the microscope leucocytes appear in great abundance surrounding the capillary vessels, and especially the glomeruli. The epithelium, of course, is markedly changed. The mottled appearance of the kidneys shows that the inflammatory process in this form of the disease begins at, and often is limited to, a number of points, instead of involving the whole organ at once, as in post-scarlatinal nephritis. The kidneys are rarely entirely disabled, as in the latter affection; and when death occurs, it is generally in consequence of septicæmia, rather than of the nephritis.

This form of renal disease is always preceded by angina of a foul, sloughy character, and by suppurating lymphatic glands and cellulitis. Suppuration of the middle ear may also precede or attend it. The quantity of albumen in the urine may be variable, though it is rarely as abundant as in the post-scarlatinal variety. Blood also may be present, but never in large quantity. There is not apt to be more than barely sufficient to give a slight tinge to the urine. Careful testings, however, show that it is *not infrequently* present, even when the eye fails to detect it. Casts and epithelium are present in only exceptional cases. The quantity of urine is generally not greatly diminished, and hence œdema, or much puffiness about the face, is not common.

The kidney lesion in this form of albuminuria is only a part of a general septicæmic condition, and death, in the majority of cases, occurs in consequence of the latter. Sometimes, however, the inflammatory process in the kidneys progresses to a general nephritis; the organs then may become choked, the urine suppressed, and death result from uræmia.

The third form of albuminuria is by far the most common, as well as the most important, and is the result of general nephritis of an acute character. It does not make its appearance until the fever has subsided, the eruption disappeared, desquamation begun, and convalescence seemingly fairly established. This form of nephritis has been characterized by various names, such as "tubal," "desquamative," "catarrhal," etc., each indicating some peculiar notion concerning its pathology. The term post-scarlatinal nephritis is now more generally preferred, because it indicates the period of scarlet fever at which this form of kidney affection occurs, without committing to any notion as to the nature of the lesion.

An examination of the kidneys of patients who have died of this form of renal disease shows that they are enlarged and hyperæmic, and present evidence of general inflammatory action. The capsule may be readily stripped off, the cortical substance is found thickened, and sometimes softened, and the glomeruli present evidence of being intensely implicated. A cut section examined microscopically shows the capillaries dilated, the glomeruli enlarged and inflamed, with proliferation and desquamation of their epithelium, hyaline degeneration of the minute arteries, and also of the capillaries of the Malpighian bodies, causing a distinct narrowing or obliteration

of these vessels. Anuria and uræmia—symptoms frequently observed in this form of disease—may be attributed to either compression of the vessels forming the glomeruli, or to the changed state of the arterioles. Klein, I believe, attributes these symptoms to the latter.

When post-scarlatinal nephritis occurs, the earlier symptoms usually make their appearance during the third week of scarlatina. This complication rarely occurs outside the limits of the fourteenth to the twenty-sixth day of the disease. Some authorities speak of cases in which the nephritis begins at a later period than the twenty-sixth day; but such instances, I am sure, are exceptional. It is not apt to occur earlier than the fourteenth day, except when the septicæmic variety of albuminuria runs into the post-scarlatinal, which, indeed, is not uncommon in the septicæmic class of cases. In such cases the albumen already present in the urine suddenly increases to a much larger amount. The other symptoms may or may not be exaggerated, but a distinguishing feature of this third variety of albuminuria is that the albumen is always present in much larger quantity than in either of the other two varieties.

Concerning the etiology of this disease, there is, I think, scarcely room for doubt that the kidneys are rendered predisposed to inflammatory action by reason of their irritated state, incident to separating the scarlatinous poison from the blood. The kidneys, after scarlet fever, have been not inaptly compared to the lungs after measles, as in either case inflammation of a fibrinous or croupous character is liable to supervene. As pneumonia may follow in mild cases of measles, so also nephritis may occur after mild attacks of scarlet fever. While patients with mild attacks of the fever are less predisposed to kidney complication than those who pass through a severe form of the disease, yet the former, through the want of proper care, or on account of too early exposure, not unfrequently suffer from this complication. The first case of post-scarlatinal nephritis I ever saw followed an attack of this character. It occurred as long ago as 1861, and, although I have no notes on the case, it made such a deep impression on my mind at the time that I shall never forget it. The circumstances were these: I was called to see a child about one year old, and found him suffering from scarlatina. The eruption was, at the time, out abundantly, and all other symptoms were well marked. My attention was called at the same time to another child, aged about three or four years, who was sitting on the floor playing with his toys. The appearance of this child was very peculiar: he looked like an excessively fat boy, so great was the anasarca. His parents informed me that, although he had been a little indisposed, the child was not at any time deemed sufficiently ill to require the services of a physician, and so none was called. The child, therefore, received no care nor treatment. On my visit the next morning I found crape on the door, and on entering the house was surprised to learn that the anasarcous child, who the day before was playing with his toys, had suddenly died during the night.

Why nephritis so frequently occurs in the declining period of scarlet fever, or during the desquamative stage, instead of earlier in the disease, is not fully understood. A disturbance of the function of the skin has been assigned as the cause, and, in a certain way, this may have something to do with the disease. There is no doubt that the renal affection, in many instances, is plainly attributable to exposure, or to currents of cold air. Chilling the surface of the body tends to check cutaneous transpiration, and thus additional work is thrown on the kidneys, which are already in a state of intense irritation, and therefore markedly predisposed to take on inflammatory action. If in mild cases of scarlatina the kidneys suffer irritation in separating the poison from the blood, in severe cases—those marked by prolonged fever, by much exudation about the fauces, and by glandular inflammation—there must be still greater irritation, for among these the worst and most fatal cases of nephritis are found. It quite frequently happens, however, that severe cases escape the malady, while mild ones are attacked. The explanation appears very plain: It is that severe attacks of scarlet fever require the patients to be kept in bed a suitable time, and in a warm room for three or four weeks, or longer, by which time the most liable period for the development of renal disease has passed; whereas, mild cases are more carelessly treated, and not infrequently exposed very freely to all kinds of weather at that period of the disease when this complication, or sequela, is most liable to appear.

In the majority of cases of post-scarlatinal nephritis, the earliest symptoms observed are slight pallor and puffiness about the face. A little investigation will then generally reveal the fact that the patient has slight headache, accompanied by languor, loss of appetite and strength, together with pain in the lumbar region. An examination of the urine usually shows that it is diminished in quantity, and contains some albumen. Ashby says he has often noticed a slight pallor or puffiness of the face in children who had no albuminuria, but in whom it appeared a few days later.

The quantity of albumen is small at first, but increases as the disease progresses, until it reaches, not infrequently, the proportion of one third, one-half, two-thirds, or even more, of the bulk of the urine. In some cases, indeed, the albumen is so great that the urine is set solid by boiling. In almost all cases there is, as the disease progresses, a gradual diminution of the amount of urine passed, and its specific gravity is usually light—varying from 1010 to 1020; but the presence of a very large quantity of albumen may raise the specific gravity to normal, or even higher. The amount of urea excreted is also diminished. The urine, on cooling, generally throws down a dense deposit, and it often presents a smoky appearance, showing that it contains a little blood, or it may be red and decidedly bloody. Examined microscopically, it shows the presence of blood-corpuscles, epithelial cells, and hyaline or granular casts, sometimes both.

In consequence of the diminished renal secretion and the altered state of the blood, transudation of

serum from the bloodvessels takes place, giving rise to anasarca, which, besides the puffiness of the face already alluded to, shows itself quite early in the feet and ankles. If not checked by treatment, it is liable to extend to all parts of the body, even to the scrotum. When excessive, the patient presents, as in my first case, the appearance of being extremely fat. The dropsy is not always limited to the cellular tissue underneath the skin, but it may also assume the form of œdema of some internal organ, or effusion into a serous cavity. In order of sequence, œdema of the lungs is most frequent; next to this there is found effusion into the pleura, the peritoneum, the pericardium, the encephalon, and in rare instances œdema of the glottis may occur. The danger from the dropsy itself depends entirely on its location. While anasarca or ascites is scarcely ever fatal, œdema of the lungs or the glottis, or intracranial, pericardial, or even pleural effusions always give rise ro alarming symptoms, and sometimes prove rapidly fatal.

The diminished amount of urine passed is sometimes the first symptom to call attention to the renal complication. As the disease advances, the amount grows less and less, until, in extreme cases, there is complete anuria. Even the urine that is voided does not as a rule contain the normal proportion of urea. In consequence of all this we may expect to find, as we frequently do, symptoms of uræmic poisoning. Among the earlier of these symptoms are headache, nausea and vomiting. Following these are somnolence, threatening coma, and convulsions. Although these symptoms are unquestionably serious, they do not necessarily betoken a fatal termination. Under prompt and appropriate treatment many patients with severe convulsions, and even in a condition approaching coma, have been so benefited in a few days as to become fully convalescent. On the other hand, not infrequently, the eclampsia continues in spite of all treatment, and the case ends in a fatal coma. It should be borne in mind that death may result in the same way from intracranial effusion. Some care is therefore often necessary to differentiate between these two conditions.

The fever in post-scarlatinal nephritis may vary considerably. Frequently there is no elevation of temperature at all. Sometimes it is normal in the mornings and shoots up a degree or two in the evenings. Not infrequently the outset of the disease is marked by a distinct elevation of temperature, which quickly subsides again to normal. Occasionally, in the midst of a normal or slightly elevated temperature, there are exacerbations of short duration. Only rarely does the temperature remain high continuously, or even for any considerable length of time. It has been noticed that an exacerbation of the temperature is sometimes followed by the passage of bloody urine; thus indicating that there had been a temporary congestion of the kidneys which was relieved by the transudation of blood into the urine. This condition may be reproduced from time to time, and at those periods when the blood in the urine is markedly diminished, or entirely absent, the temperature falls to normal. In uræmia it is generally sub-normal.

There is a notable peculiarity about the pulse in post-scarlatinal nephritis. While it is generally very rapid in the early stage of scarlatina, it is now found considerably retarded, often slower, indeed, than in health, and sometimes irregular. It may also remain slow even when there is considerable elevation of temperature. A pulse of sixty-eight in a child is not uncommon. It may, however, be accelerated by some accidental cause, or by the approach of death.

Affections of the eye are sometimes met with in this form of nephritis. Some writers have described a special form of retinitis, which is said to arise quickly and cause various degrees of loss of sight, without producing total blindness. Although the course of this affection is spoken of as protracted, the prognosis is considered favorable. This form of retinal disease is believed to be something quite different from that which so often occurs in the course of chronic renal disorder, and which is characterized by gross structural changes in the retina of a permanent nature. The affection of the eye most liable to occur in post-scarlatinal nephritis is *amaurosis uræmica*. This is an acute, suddenly-appearing symptom sometimes met with in uræmic poisoning, and must therefore be reckoned amongst the group of symptoms of that disorder. The amaurosis is happily transitory, disappearing often as quickly as it comes. On arousing from a state of unconsciousness, the patient sometimes finds himself entirely blind; this may continue for two or three days, but rarely lasts longer than ten days. The ophthalmoscope fails to reveal, so far as I know, any pathological alterations of the visual organ which could account for the sudden blindness. It has been suggested that the cause may lie in simple œdema of the retina, which is not improbable.

The duration of post-scarlatinal nephritis varies according to its intensity. In the mildest cases the symptoms may all disappear in two or three days. In a fairly marked case the albuminuria may last for two or three weeks, disappearing very gradually. Even after the disappearance of the last trace of albuminuria, some other abnormal products frequently continue in the urine for a long time. The form of nephritis characterized by anasarca and dropsical effusions may last from one to two or three months, and sometimes even longer. With the disappearance of the dropsy the albumen in the urine usually diminishes, though it often continues to be present in a small quantity for a long time, even after the patient believes that he has fully recovered. Occasionally the nephritis becomes chronic; or, months after the apparent recovery, the patient, from exposure, or some other cause, is seized with a return of well-marked albuminuria and possibly dropsy, and may die of chronic Bright's disease. When death results from the acute form of the disease, it may ensue in the first, though more frequently not until the second or third week.

Treatment.—But little attention need be given to the first form of albuminuria. If it be, as is claimed, merely febrile albuminuria, it will disappear with the fall of temperature. In the second form of albumi-

nuria, or that depending on septic changes in the kidneys, the treatment should be aimed more especially at the local and systemic conditions which give rise to the renal disorder. Fortunately, in this form of the disease the function of the kidneys is but little disturbed; it is only when general nephritis supervenes that their secreting power is seriously affected. Therefore, in the third form of the disease, or post-scarlatinal nephritis, treatment is always required, and often that of the most prompt and active character is demanded.

In the first place, it is highly important that this complication or sequela should be prevented. Therefore, during convalescence from scarlet fever, the patient should be properly clothed and kept in-doors, and in a uniform temperature for three or four weeks after the fever has disappeared, or until desquamation has entirely ceased and the new epidermis acquired sufficient thickness to afford proper protection. The urine should be examined for albumen every few days, and as soon as any is discovered the patient should be put to bed in a room having a uniform temperature of 72° to 75° F. The diet should be liquid: there is nothing better than milk. An effort should be made at once to relieve the hyperæmia of the kidneys. For this purpose warm water baths, at a temperature of 98° to 100°, continued from fifteen to twenty minutes, may be used; after which the patient should be returned to the bed and covered with blankets.

Purgatives may be used early, and even repeated later on with advantage. They should be selected from that class which produces watery stools. Perhaps one of the safest purgatives, and at the same time most useful, is the *pulvis jalapæ compositus*. This may be given in doses of ten grains to a child five years old, and repeated as circumstances may require. Its action may be increased by allowing the child to drink freely of a solution of bi-tartrate of potassa—say in the proportion of a teaspoonful of the salt to a tumblerful of water. It should be borne in mind that patients in this condition are apt to be anæmic, and therefore purgation should not be carried to excess.

Drugs producing diaphoresis should also be employed—such as citrate of potassium, acetate of ammonium or potassium, and sweet spirits of nitre. When the urine is greatly diminished in quantity, and serious symptoms threatening, there is no drug so efficient as pilocarpine. This may be administered to children from two to six years of age, in doses varying from the one-fortieth to one-twentieth of a grain, and repeated every six hours. In case the stomach will not tolerate it, it may be employed hypodermically—say in doses of one-twentieth of a grain to a child of five years. It acts both as a diaphoretic and diuretic, and it also increases the salivary secretion. Any depressing effect liable to be produced by it may be guarded against by the simultaneous administration of stimulants.

When there is great anasarca and difficult respiration, with the urinary secretion suppressed or greatly diminished, I have found no agent so useful as hot-air baths. Each bath should be continued for about one hour, and may be repeated once or twice daily, according to the urgency of the case. When properly used, these baths are far more certain to produce not only diaphoresis, but profuse diaphoresis, than any drug or agent that I have ever employed. I have seen patients gasping for breath, and whose lives seemed in imminent danger, relieved of this distressing symptom by one or two such baths.

Diuretics of not too stimulating a character are always useful in the latter stage of the disease, and they may indeed often be employed with advantage in the early stage. Digitalis is one of the most serviceable, and it may be employed from the very commencement of the malady. I think the best way of administering this drug is in the form of an infusion. It may be given in combination with acetate of potassium, as follows:

℞.—Potassii acetatis . . . . . ʒ ij
Infus. digitalis . . . . . fʒ iij
M. Sig.—Teaspoonful every three hours to a child of five years.

Meigs and Pepper recommend the following mixture:

℞.—Potassii bitart. . . . . ʒ j
Sp. juniper. comp. . . . . fʒ ij
Sp. æth. nitros. . . . . fʒ j
Tr. digitalis . . . . . ♏ xv
Syrupi . . . . . fʒ v
Aquæ . . . . . fʒ ij
M. Sig.—Teaspoonful every two hours to a child from two to four years of age.

Local measures may be employed over the region of the kidneys. Leeches have been used; but as there is always a marked tendency to anæmia, leeching is only admissible in robust patients. Dry-cupping, however, may be of service. Poultices are useful, and may be applied in any case. I am in the habit of using ground flaxseed and mustard, in the proportion of fifteen tablespoonfuls of the former to one of the latter. In this way the poultice is made somewhat more irritating.

For the uræmic convulsions, I know of nothing better than the warm water bath, bromide of potassium, or hydrate of chloral. The bromide should be given in large doses. To a child three years of age, five grains may be administered every fifteen minutes until two or three doses shall have been given, provided the convulsive movements continue that long; afterwards the dose may be repeated at longer intervals. Hydrate of chloral is doubtless more efficient. Five grains of this drug introduced into the rectum of a child from three to five years of age, will generally control the convulsive movements within fifteen or twenty minutes. Inhalation of chloroform has been recommended; it doubtless will give temporary relief. But whatever antispasmodics may be employed, it is highly important that the efforts to relieve the choked kidneys should be continued at the same time.

After the acute stage of the renal disease has abated, ferruginous tonics are found of great service. There are two preparations to which I am very partial. One is a solution of citrate of iron and ammonia, with sometimes the addition of a little carbonate of ammonia; and the other is Basham's mixture.

A CASE OF RENAL CALCULUS.

By ERNEST B. SANGREE, A.M., M.D.,
Demonstrator of Histology in the Medico-Chirurgical College of Philadelphia.

LATE one night I was called out to see a young lady, twenty-three years of age, who was suffering from what at first seemed to be an attack of lumbo-abdominal neuralgia. To abate the pain which was intense, I gave her a subcutaneous injection of morphine sulphate gr. ¼, and also a full dose of chloral hydrate by the mouth. These soon relieved her in great measure.

The outset of the pain she described as beginning over the right kidney, and from there extending along a line parallel with the ureter and down the inner aspect of the thigh. It also radiated over to the center of the abdomen, in the line of the lumbo-abdominal nerve.

On questioning her I learned that she was from the country, and in the city merely on a visit, and that she was then taking medicine for neuralgia.

These attacks had begun over a year before, with one of great suddenness and severity, coming on after a carriage ride, and they had occurred every three or four weeks since, in spite of all medication. A ride on the railway, or in a carriage over a rough road was likely to produce an onset, as was also any active exertion, such as sewing on a machine, and for this reason she had been compelled to give up her occupation—that of a dressmaker. During the last year she had lost considerably in weight. Within the same period she had noticed blood in her urine three times, though this had happened not immediately before or after an attack, but in the interval. She constantly experienced a dull pain over the right kidney, which was slightly increased by pressure.

I found upon careful examination that her urine presented the following characteristics: Sp. gr. 1.018, reaction, acid; color, light amber, and clear with the exceptions of a few shreds of mucus; no albumen, no sugar. After standing twenty-four hours a flocculent deposit appears, which the microscope showed to be composed of mucus, amorphous urates, much epithelium from the bladder, and numerous crystals of oxalate of calcium. Many of these crystals were of very large size, and though she suffered no pain in urinating, yet I think the extraordinary amount of bladder epithelium must have been due to the erosive action of these angular crystals. All forms of oxalate of lime crystallization were represented: octahedral, dumb-bell, and the different variations such as oval, spherical, and the like.

As neither pus nor blood was present, there could not be cystitis. Again, the failure to find pus, together with the comparative insensibility of the kidney to pressure, showed there was not calculo-pyelitis and that the stone must therefore be embedded in the substance of the kidney. The diagnosis was accordingly an oxalate of lime calculus in the body of the kidney.

For treatment, alkalies were given in order to keep the urine nearly neutral. She was to take plenty of diluents, and abstain from foods rich in oxalates. In addition to this she should have rest as nearly absolute as possible, in the hope that the stone may become encysted and trouble her no more. If it does not, however, and the attacks should persist, and perhaps increase in frequency and violence, making life a burden to her, then an operation for the removal of either the calculus alone or the kidney along with it must be seriously discussed.

INSTANCES OF THE HEREDITARY INFLUENCE IN THE CAUSATION OF MULTIPLE PREGNANCY.

By CHARLES MEIGS WILSON, M.D.,
Physician in charge of the Philadelphia Lying-in Charity.

THE following cases are reported on account of their rarity; two came under my personal observation, and the third was related to me by a thoroughly trustworthy person. What subtle influences lead to the habit of multiple fecundation, and how that habit is handed down from one generation to another, or may even be manifested through several succeeding generations, I am at a loss to explain. That such idiosyncrasies do, however, exist, cannot be doubted, in view of the fact that while they are rarely found, yet several instances have been recorded. On August 4, 1889, I delivered, after an easy labor, in the maternity ward of the Lying in Charity, Florence B., of two male children. They were undersized, one weighing four and one-half pounds, and the other five and three-quarter pounds Their placentæ were entirely separate; the sacs were, however, fused together. Six weeks afterwards I delivered her twin sister of two male children, both undersized and of a combined weight of nine and one-quarter pounds. Upon making inquiries of the sisters I found that their mother was a twin, and that she had twice given birth to twins. Their mother had borne female children only; hers were all legitimate pregnancies. The two sisters that I attended were both primiparæ, and were both illegitimately pregnant. I have instituted careful inquiries to trace back, if possible, whether this habit existed in any former generations of the family.

The second case I wish to record is that of a woman, Mrs. James S., whom I have thrice in succeeding pregnancies delivered of twin children, and who was herself a twin.

The third case is that of a patient who showed me corroborative evidence in the record of his family births of the fact that he was one of three succeeding sets of twins.

INDUCTION of artificial labor is done simply by a method recently brought out by Pugliatti, but which the translator has practised many years with satisfactory results. Patient is brought to the edge of the bed, a bivalve speculum is introduced, and an antiseptic injection administered. A clean, aseptic, elastic bougie is gently introduced as far into the uterus as it will pass; the remainder is coiled up in the vagina. If pains do not begin in three hours, another vaginal injection is given and followed by the introduction of a larger bougie.

Hydrotherapeutics.

A PLEA FOR THE PRACTICAL UTILIZATION OF HYDROTHERAPY.[1]

By SIMON BARUCH, M.D.,
Attending Physician New York Juvenile Asylum and Manhattan General Hospital.

[Concluded from page 781.]

WINTERNITZ dwells with his usual clearness and scientific precision upon the reasons of the improvement obtained in phthisis by hydrotherapy. He quotes Dettweiler, whom you all know as the most successful phthisistherapist, in its favor. Winternitz applies continuous moist compresses to the chest, covered by dry flannel, in most cases. For the hectic fever he uses wet packs, followed by rubbing in the wet sheet, or the rain bath of one minute. Among 169 cases of phthisis of various types, treated at his institute since 1874, 76 per cent. gained in weight. The cases are given in detail, and the result shows that in 58 cases of florid phthisis with hectic fever, in sixteen a cessation of the process was obtained. In the majority of the cases not improved locally, the general condition, appetite and strength were enhanced, the fever and sweating diminished.

At the Montefiore Home, which is a hospital whose rules forbid the admission of any curable disease, the cases of phthisis are of the most pronounced types, usually refused at other hospitals. Even among these desperate cases, all of which have usually had the prevailing medicinal treatment, the result of hydrotherapy in phthisis has been striking, as a few brief histories, for which I am indebted to the efficient senior house physician, Dr. L. Ettinger, will show.

G. S., aged 28, consolidation of apex front of right lung, admitted Dec. 23, '88, with pain in chest, severe cough, yellow expectoration, severe chills, followed by fever and sweating. Dry pack, cold wash off, followed by wet sheets. Result, entire abatement of symptoms, no physical signs of consequence. Discharged, May 1, '89 (weighing 149 pounds), at his own request.

J. S. Double chest lesion. Wash off and wet sheet. Complete cessation of cough and expectoration. Weight increased from 115 to 126 pounds.

A. L. Right apex lesion. Cold wash off (water at 65° F.), followed later by wet sheet. Marked improvement in all symptoms. Weight increased under hydrotherapy, in two months from 124 pounds to 134½.

H. F. Left upper lobe. Marked emaciation, extreme anæmia, cough, expectoration, repeated hemoptysis, weight 96 pounds. Arsenic, creosote, cod-liver oil, cold wash off daily. Complete disappearance of hemoptysis, almost of cough, no fever, presents picture of health, weight 104 pounds, no râles, decrease of dullness.

N. R., aged 37. Right apex lesion. Sick four months with cough, expectoration, loss of flesh, hemorrhages and fever, very feeble, anæmic, emaciated. T. 102. P. 110. R. 31. Weight 103½ pounds. Severe hemorrhage directly after admission. Did not improve from May 19 to June 10, when daily cold wash off was begun. Improvement rapid, anæmia disappeared. Discharged at her own request, with a gain of seventeen pounds in weight.

Lilly W., aged 9. Double mitral lesion. Admitted extremely feeble, anæmic and hopeless. Received cardiac tonics, iron, cod-liver oil (all of which she had before admission). Wash off at 65° F., succeeded by wet sheet daily. Is now in excellent spirits, walks to public school daily.

Chronic rheumatism and gout, those most obstinate maladies, have long been eloquent witnesses to the value of hydrotherapy. The immense number of cases cured by Priessnitz, many of whom belonged to the highest ranks in England, France and Germany spread the reputation of hydrotherapy far and wide among the lay people. The triumphs of the German peasant were observed by an eminent German physician, Schedel, and thus communicated to the profession. These cases so often revert to the empirical hydropaths, after prolonged and ineffectual medicinal and dietetic treatment, that they form the largest contingent of patients from whom the empirics derive the greatest reputation and financial results. In France, however, such cases are usually sent to men who, like Duval, are educated hydrotherapists.

From the Montefiore Home were discharged two cases of chronic rheumatism, cured, both of whom came there, like all other cases, to spend their last days in comfort.

Constipation is one of those minor functional ailments which give us no end of trouble. After failure of medicinal agents, I have obtained such excellent results by electricity and hydriatic measures that I am tempted to a brief reference. A few cases will illustrate the treatment.

M. G., for whose history I am indebted to Dr. Ettinger, of the Montefiore Home. History of exposure to lead, being a painter; marked abdominal distention, indefinite pain, sallow, anæmia, anorexia, severe constipation, which has resisted all medicinal measures before and after entering the Home. His constipation, as well as general condition, were regarded as hopeless by all his medical attendants.

March 15th. Weight, 139 lbs. Dry pack and cold wash off daily. No effect.

20th. Wash off preceded by hot fomentations to abdomen. Enema of water at 45° F., to be retained, one-half hour before wash. Large laxative enemata necessary to move bowels daily.

April 1st. Girth diminished, abdomen soft; still requires large enemata.

April 3rd. Pil. aloes and mastich one before each meal; no effect on bowels for three days.

10th. Entire disappearance of abdominal swelling; cold enema is retained; bowels regular, once or twice daily; reduced to one pill at bedtime.

May 1st. Discharged at his own request, cured; weight, 149 pounds, a gain of ten pounds in six weeks.

M. A., æt. thirteen, inmate of N. Y. Juvenile Asylum, recorded by Mr. Henry Carpenter, student of medicine; suffered from constipation always; had taken magn. sulph., and other laxatives, also cold

[1] Read before the New York Academy of Medicine, November 1, 1887.

baths and massage, to improve general condition; four c. c. pills without effect. A second dose was followed by a scanty stool. Cascara had no effect. Her appetite was poor. On the 23d Aug., I ordered all medication stopped; an enema of ʒ vj of water at 65° was given, to be retained, and finally strong Faradic current over colon once daily for twenty minutes. A linen compress wrung out of water at 60° F. was constantly worn, renewed three times daily with a wash off. A small stool followed, an hour after first cold enema; on the second day another followed four hours after enema. A rash appeared under compress on third day; current was increased. On the fifth day she had the first normal stool; appetite began to improve. Pain was produced by enema on the twelfth day; ordered it every other day for two weeks. She is now in perfect health and her bowels regular. These enemata of six ounces of cold water, it should be noted, do not act mechanically, but as stimuli to the innervation of the intestine.

An illustration of the tonic and sustaining effect upon the nervous system of cold ablutions is furnished by the case of M. E., a patient at the Montefiore Home, for morphine habit. He was a pitiable object, emaciated and haggard to the last degree; pulse 150. The quantity consumed by him reached two ounces of Magendie's solution hypodermically each day. This was slowly and gradually reduced in the course of three months, while patient's strength was sustained by good food, stimulants and cold ablutions after dry pack. He is now in excellent condition; his face is full, eye bright, and the habit entirely removed.

The tonic effect of hydrotherapy, so well illustrated in this case, is clinically established by the general results in the Montefiore Home for Chronic Invalids. This is really a home for incurables, but does not bear that title, because it would be equivalent to Dante's inscription: "They who enter here leave hope behind." It is a positive rule that no case be admitted that has not been pronounced incurable by other hospitals or physicians, and whose incurability is not vouched for by our examining physician. The benevolent gentlemen of the visiting committee satisfy themselves personally of the facts; and yet, among these desperate and hopeless cases, the last report records six cured and thirty-five improved, eight of whom have returned to their homes and daily work. Can clinical testimony be more convincing?

Time forbids my entering upon that most fruitful of all fields for hydrotherapy—the febrile diseases. In these the third method referred to, viz., the arming of the patient for the battle with disease, is illustrated. As I have already spoken and written a good deal upon this subject, I must complete this rapid review by merely referring to the fact that statistics whose sources are unimpeachable have demonstrated that the mortality of typhoid fever has been reduced from 25 per cent. to 2 per cent. by the systematic bathing of Ernest Brand's method. I am glad to learn that Drs. Flint and Dana have introduced this method into their divisions in Bellevue Hospital, and that Dr. Peabody uses it in the New York Hospital. The latter emphasizes one point that cannot be too often reiterated. He says that "cold sponging, in many cases, is wholly inefficient; many lives have been lost by a timid temporizing with this modification (of bathing)." This is but too true. I desire to reiterate the necessity of implicitly following an exact technique in hydrotherapy. Wrapping a typhoid patient in a sheet and sprinkling her with ice-water, as was done to my knowledge in two metropolitan hospitals by able gentlemen who are teachers of medicine, is *not cold bathing*. They reduced the temperature, but the patient died. The bath must be adapted to each case; and the fact should never be lost sight of that its object is *not* to reduce temperature, but to refresh the nervous system, and enable the organism to withstand the lethal influences at work in the regular progress of the disease.

As an illustration, I may mention a case now under treatment in my service at the Manhattan General Hospital. I found him in the fifth week of a typical case, after having had hemorrhage and pneumonia, with a feeble, rapid pulse; temperature range from 101° to 104°; mental confusion; sluggish peripheral circulation; altogether an unpromising case. The usual bath at 65° for fifteen minutes would have sent him into an irremediable collapse. The nerve centers required arousing and refreshing. I ordered a sheet, partly wrung out of water at 70°, to be wrapped around him for ten minutes, and covered by a blanket, followed by an ablution with water at 65°. Temperature was reduced to 101° by this procedure; he became brighter. Compresses wrung out of water at 70° were kept on his abdomen so long as his temperature was above 102°. Patient has had no delirium since first wet sheet, to which he objects most strenuously, however.

Gentlemen, craving your indulgence for having so long detained you, I must now bring this imperfect sketch of hydrotherapy to a close. I trust that in this plea for its practical utilization, I have shown that modern hydrotherapy is no longer an empirical method. Though of such parentage, and nurtured into active life under such environment, its aims to-day are definite, and it explains every process upon well-proven premises. This is science, in its true sense; this is the goal of medicine for which ages have striven in vain; a goal, though not yet fully attained and probably not attainable, which is, nevertheless, so replete with promise that he who will strive in the same direction will be gratified by the result of his labors. This goal has not been reached in the treatment of disease, because hitherto the men who, like Hippocrates, Hufeland, Hahn, and Currie, realized the empirical value of water, were more or less in the dark regarding the organic processes of life in health and disease. The grand physiological and chemical discoveries of the present time have enabled men like Winternitz, Delmas, Pleniger, and others to place hydrotherapy on a rational basis, so that to-day we may say with Plohn, "As in no other department of medical activity, we find here a method whose advances have been individually and physiologically tested and adapted to the laws of the living organism, to be converted into a rational curative

measure for special purposes of application; whose therapeutical results are the more reliable since they have been often corroborated by empiricism, prompted by a spirit of impartial and fruitful research. That which medicine of the Nineteenth Century has struggled to attain since it awoke from the desperate period of absolute skepticism—namely, practical, prophylactic, and therapeutical action, based upon the results of theoretical research in its whole extent, thereby being in a position to give the practical physician that security of which the physicist and chemist boasts—all this hydrotherapeutics is on the way to accomplish."

In conclusion I desire to reiterate, however, what I have said before—that I do not regard hydrotherapy as a universal measure, which will displace the well-tried medicinal remedies, whose value has been carefully tested by able and conscientious men, and which I would be the last man to dispense with. But I would urge upon you to test it fairly and fearlessly. You will find it an auxiliary of no mean power, especially in those trying cases which have baffled your best directed efforts.

47 E. 60TH STREET, NEW YORK.

The Polyclinic.

MEDICO-CHIRURGICAL HOSPITAL.

OPERATION UPON NASAL SEPTUM.

A YOUNG man, seventeen years of age, with a deformity of the nasal septum, the cartilage being bent to the left and almost completely closing the left nostril. The patient being etherized, an incision is made close to the left ala of the nose. A straight bistoury is then passed into the wound and the cartilage cut from the vomer, seized with a strong pair of forceps and forcibly bent over and straightened. Having arrested the hemorrhage, the nostril is washed and plugged with iodoform gauze. The incision being so small, it does not require to be stitched. —*Pancoast.*

SYPHILITIC ULCERS OF FOOT.

Wm. S., fifty-three years old, single, a truckman or farmer's help, presents himself by the aid of a friend only, and when asked to walk, goes upon hands and knees. A case of old frostbite, got six years ago, by sleeping in an out-building.

His stockings being removed, it is seen that all the toes of one foot have been removed, and all but the smallest toe of the other foot are also minus. There are also ulcers of unhealthy hue and sluggish appearance, some flat and others in the shape of sulci. There are also large callosities below, and the anterior end of the calcaneum is much lower than the posterior end. Moreover, on placing the hands on the two feet at the same time, we notice that one is much warmer than the other, though the same warmth of foot-wear has been used. Examining still closer, it is seen that, while there is a generally bluish and forbidding color to each foot, the one of low temperature looks worse.

On inquiry, it is found that the ulcers have plagued the man for months. The unhealthy look, peculiar color, and long persistence of the ulcers hint of specific taint. Again inquiring, the patient confesses that he has had primary and secondary syphilis.

Treatment.—First, externally, thorough washing of the ulcers with a 1 to 1000 solution of the corrosive sublimate wash, using as hot water as is comfortable, then drying carefully with sublimate cotton, dusting thoroughly with iodoform, and covering with the same kind of cotton and a roller bandage. Secondly, for internal treatment, we will put him on the iodide of potash, as in the following formula.

℞.—Potassii iodidi . . . . . ʒ ij
Syrupi sarsaparillæ . . . . . ℥ ij
Aquæ puræ . . . . . q. s. ad ʒ vj—M.

Take a dessertspoonful four times a day.

We will ask the patient to report at our service on Friday. We will watch the effect of the internal treatment particularly, changing, if need be, to other of the iodides, or to the use of corrosive sublimate. —*Stubbs.*

PHILADELPHIA HOSPITAL.

OPHTHALMIA NEONATORUM.

YOU know that it is not uncommon, several days after birth, to have a slight redness of the eyes of the child, with a certain amount of mucus. If no gonorrhœal virus is present, it soon gets well. Here are two cases of purulent inflammation of the eyelids and conjunctiva, in which the lids are swollen, tumefied and red; and there is a copious secretion of pus. In this child you see it in the stage of defervescence. It was formerly supposed that inflammations of the eye rose from any micrococcus; but when you get a case of purulent inflammation of the new born, it is due to the gonococcus. Prognosis is bad in neglected cases, for ulceration, with perforation and loss of one or both eyes, occurs. During the summer just past we had a case of gonococcal infection, and, in spite of all we could do, both eyes became infected and were lost. Treatment is first prophylactic, as the vaginal douche to the mother at the beginning of labor; but the cocci shelter themselves so much in the folds of the mucous membrane that the antiseptic solution cannot reach all of them; still the douche will mitigate the severity of the case. Crede's method is to drop a few drops of a two per cent. solution of nitrate of silver in the eyes one-half hour after birth, and follow this by flushing with a very mild salt water bath. Thoroughly cleanse the eyes by a continuous stream from a douche, and run the stream from the inner to the outer canthus, to avoid infection of the other eye. Usually both eyes are infected; but if one is not, close it with antiseptic gauze and cotton which has been salicylated, to protect it from infection. A saturated solution of boracic acid may be used *ad libitum*, or you may use mercury bichloride, one to ten thousand, or a two per cent. nitrate of silver solution. If the case promises to be severe or long, put the iris at rest by atropia. May use boracic acid solution every hour, but when the nitrate of silver is to be used, apply it yourself. Always caution the family of the contagiousness of this disease. —*Davis.*

ST. LUKE'S HOSPITAL.

SERVICE OF DR. B. FARQUHAR CURTIS.

J. V. D. Young, House Surgeon.

LAPAROTOMY (EXPLORATORY) FOR ABDOMINAL TUMOR.

THE case which I present to you to-day is one of great interest. The symptoms are obscure and the difficulties of diagnosis correspondingly great. The history is as follows:

Mrs. ——, aged 33, Irish, nine years in the United States, married seven years, last confined fourteen months ago, weaned baby six weeks ago, has suffered with leucorrhœa since marriage, and dyspareunia for the last six months. Menses appeared at the age of thirteen; last menstruated, October 12.

Oct. 6. Complains of pain in right side of abdomen (iliac fossa), pain extends over whole abdomen, but is most marked in lower part. The pain is paroxysmal, bowels constipated, were moved by large doses of magnesia (for the first time in seven days).

Oct. 11. Complains of flushes of heat, thirst, chilly sensations, anorexia, nausea, vomiting, has no headache.

Vaginal examination: Cervix lacerated on right side, slightly softened, os patulous, uterus as a whole slightly prolapsed and displaced to the right.

Bi-manual palpation: On the right side a globular mass, extending up to the umbilicus and two or three fingers width to the right of the median line; the mass depresses the vaginal vault, and is somewhat painful on pressure. Practically, the same conditions exist on the left side. The uterus is immobilized by this mass.

The question before us, is the nature of this mass or tumor. The symptoms are not distinctive or even suggestive of any particular lesion. The differential diagnosis, we believe, lies between hæmatocele, parovarian cyst, and extra-uterine pregnancy. The symptoms complained of on the eleventh, heat, flushes, thirst, chilliness, etc., lead us to favor hæmatocele, as, although slight, they may be regarded as indicating internal hæmorrhage.

Since Mr. Lawson Tait called attention in his lectures on "Ectopic Gestation" to the primary tubal origin of almost all extra-uterine gestations, hæmatocele has been regarded with unusual interest. Though for many years the relation of a ruptured tubal pregnancy in causing hæmatocele was recognized in some cases, it was not until Mr. Tait called attention to this fact, that it was suspected that tubal pregnancy was so important a factor in the pathology of this lesion, and now, in cases of hæmatocele, we search most eagerly for fœtal structures to sustain or refute this view. The history of this case does not aid us at all on this point. The woman weaned her child only six weeks ago. Menstruation occurred on the sixth, apparently normal in character. The cervix is slightly softened, and os patulous, it is true, but these are not distinctive, and may readily be ascribed to other causes than pregnancy. Another fact which would tend to make the discrimination against the existence of tubal pregnancy stronger is, that there has been no long period of sterility.

Therefore, an accurate diagnosis being impossible, the woman's condition demanding immediate relief, the case is one eminently fitted for an exploratory laparotomy. The operation which we shall do to-day is, therefore, an exploratory laparotomy, for supposed hæmatocele with the possible occurrence of a ruptured tubal pregnancy.

Making an incision through the linea alba, we are now down on what we regard as the peritoneum; further examination confirms this: the peritoneum is much thickened, and the cyst wall is strongly and closely adherent. The adhesive inflammation which has bound the cyst to the peritoneum, renders it difficult to distinguish one from the other. Before opening the cyst, as we are in doubt as to its exact nature, we will aspirate with an exploring needle and syringe. The fluid, as you can see, is nothing but blood; therefore our diagnosis of hæmatocele is sustained. Incising the cyst, nothing escapes but blood.

At the bottom of the cyst, I feel a hard body. As we may suspect the primary cause to have been a ruptured tubal pregnancy, is this the fœtus? The light is very poor to-day, so it will afford me a good opportunity of illustrating the value of the electric light in abdominal surgery. This small electric lamp is run by an ordinary galvanic battery; we can place it in any position, at any angle, and by its aid search any porition of the cavity. The hard body mentioned is a tense secondary cyst, which I have caused to rupture by pressure. It contains nothing but blood, and a smaller cyst. This I also rupture, and in it I find several hard particles; on close examination, I find these to be true bone.

The correct diagnosis therefore is: tubal pregnancy of less than ten weeks' duration, rupture of the tube into the broad ligament, and subsequent hæmatocele.

We will now complete the operation by stitching the cyst wall to the abdominal wall, close off the peritoneal cavity, introduce drainage tubes, and sew up the abdominal wall in three layers with buried animal sutures.

K. B. P.

THE power of absorption of the organs has been investigated by Pisente, who arrives at the conclusion that the classical theory of the causation of ascites, that the obstruction to the portal circulation, which produces stasis of and transudation through the vessels, is the chief factor, is erroneous. By his experiments it is demonstrated that an additional factor is furnished by the diminution or the total loss of power of absorption of the liver, spleen and gastro-intestinal canal. As this is actually proven, we may conclude that the disappearance of a fluid from the abdominal cavity is determined by two factors:

a) By the cessation or diminution of the process of transudation; and

b) By the restoration of the absorbing powers of the other organs (intestinal canal) entrusted with this function.

Professor Pisente thinks that this second factor, first discovered by him, must receive deserved consideration.—*Cent. f. d. Med. Wissensch.*

THE NERVOUS ELEMENT IN UTERINE DISEASES.

A SUBJECT of greater scope, and one in which the field for speculative theorizing and practical investigation cannot be surpassed, is that of the study of the nervous element in disease. So various and protean are the forms in which the disturbances of that as yet unsolved mystery—the nervous system—loom up before the baffled and distracted physician, that, like the hydra-headed monster of mystic fame, seemingly one almost unconquerable neurotic foe is no sooner overcome and triumphantly laid in his untimely grave, ere two others as complex and intricate phases of the same phantasmic enemy spring into existence, to defy and terrorize the too-exultant victor. To undertake the development of such a subject as the neuroses, in all of their many aspects and bearings upon things medical, is a work too vast and comprehensive for other hands than those of the neurologists. We can devote here but a few lines to some speculation upon one side of the subject only, namely, its gynecological bearing, as suggested by the scholarly paper of Professor Goodell, which appeared in a recent number of the *Medical News*.

Who has not met at some time in his professional career, and often only too frequently, with the neurotic woman; and who is not thoroughly acquainted with her time-honored history of repeated visitations by each new and untried physician, with the inevitable result—failure in obtaining the eagerly-sought-for relief from her miserable condition, till, despairing of ultimate success, and yet ever lured on by the fleeting image of final restoration to health, she sinks at length into apathy and confirmed invalidism? How often do we find that we ourselves have been treating, as a case of cervical endometritis, or of uterine loss of tonicity, what is in reality the outcome of a condition of neurasthenia, allowing the teachings of a dogmatic empiricism to over-cloud our higher power of inferential reasoning!

Here, as Dr. Goodell has so emphatically laid down, is the great medical error of the day: in confounding the simple, local condition to which the attention may happen to be directed by the peculiar manifestations of the neurasthenia, with the more serious constitutional condition; in treating the former for the latter, and in thus allowing ourselves to be developed into symptomatic dogmatists rather than into conscientious rationalists.

That there is an intimate relationship existing between the sexual organism and the central nervous ganglia, is a truth as absolute as is the existence of these organisms; but in what this relationship consists, and how a diseased condition of the one will be productive of a reflex disorder in the other, we cannot say. That such is the case, however, is beyond all need of further assertion. Regarding this as conclusive, it is patent that in a broad and intelligent study of every gynæcological patient, the rôle played by the nervous system, in the production of the group of symptoms displayed, merits of primary consideration. Notwithstanding this, however, it is a curious, though self-evident, fact that, in the vast majority of instances the nervous element is either only casually thought of, or still worse, entirely overlooked; or on the other hand, the greater predominance of the nervous phenomena may entirely overshadow their true causation—a disease or perverted condition of the sexual apparatus—and the case be regarded as purely neurotic. The subject thus presents itself in a two-fold aspect, entirely sexual and entirely neurotic in their respective characteristics.

What, then, is the outcome of these considerations? How can we remedy this existing evil? This is the question which must necessarily first arise in a serious review of the field which is before us. We firmly believe that there is and can be but one solution to this problem, and that it lies in a fundamental change in the method of medical education, with a view to broadening the scope of the specialists—of the gynæcologist, in the point in hand—so that each patient coming before his notice, will be treated not simply and wholly as an uterine case, but as a complex organism of which the generative portion is but a factor and most often but a minor factor. The necessity of such a course is generally granted. As one of our leading specialists in the surgical domain has wisely said: "A true specialist must necessarily be first a thorough physician in every respect." Let the day dawn when the specialist will become more latitudinarian in spirit, leaving the narrow channels of specialism, as it is now generally understood, for the broader fields of systematic rationalism, and he will become a specialist in the truer sense of the word, and there will be less and still less occasion for the complaint of the abuse of treatment, uterine or otherwise, from mistaken diagnosis.

HOG cholera rages in Kansas.

THE HIGHER PLANE.

"The highest and only duty of a physician is to make people well."
—*Organon.*

AFTER quoting this sentence, a late number of a homœopathic contemporary observes that, "viewed in the light of this axiom, most old-school current literature is very profitless reading." In illustration, the severe writer cites one of our most able journals, of which he says that "many brilliant experiments are chronicled, many facts in physiological materia medica elicited; but very rarely anything of permanent value in applied therapeutics."

Even taking the sentence just as it stands, the logical mind will find it somewhat difficult to imagine how "many facts in physiological materia medica may be elicited," with little or no result in the way of applied therapeutics. Our contention, however, is not against this particular assertion—for it is not worth noticing—but it is against the underlying spirit—one that is all too common among the youth of these practical times, and too much encouraged by those whose years should be suggestive of wiser counsel. We allude to the rapidly-growing tendency to estimate the value of every piece of knowledge in accordance with the amount of dollars it is likely to bring in.

Public sentiment in this country, unfortunately, does not require of the medical profession a high standard of general learning.

The family physician is chosen, even among the more educated class, on account of the church or lodge to which he belongs, the street on which he lives, the society in which he moves, according to the cut of his beard, or some other agreeable physical characteristic, rather than because of any particular skill as a physician or attainments as a scholar and a man of broad culture. We have known, with excellent practice among intelligent people, physicians who said "I done," "I seen," and "them" for "those." Indeed, there is a more or less popular notion that physicians are born, that the medical curriculum, with its requisite degree, is only a legal form, simply to keep everybody from practising the healing art, and that boorishness of behavior, negligence in dress, solecisms of speech, and looseness of morals are only the natural concomitants of innate genius. Beneath these trifling accidents lies the finished physician.

How wide-spread is the belief that intemperate doctors are always the best. The physician of the novel is generally a drunkard; but always a man of supernatural brilliancy when out of his cups. Yet all this, in spite of the patent fact that one who habitually muddles his brain with alcohol cannot command equally as well as a strictly abstemious man all those powers of judgment with which nature and education have endowed him, powers that are nowhere more severely tried than in many of the positions in which the physician is placed.

Thus it happens that a young ignoramus may leave his bucolic pursuits, attend lectures at some medical school for two or three years, buy a practice, and with the assistance of a few drugs and a book of prescriptions, make a comfortable living as a professional man

What advantage will it be to him to know the histological characteristics of the intestinal canal, or the pathological appearance of the lungs in pneumonia? Will the people give him any more dollars because of such knowledge? No. Well, then, rather than spend time in reading of physiological experiments, or in studying pathological processes, he had better devote those hours to hobnobbing with Brown or Jones. They might call him in some day, if they fall out with their regular physician. He needs no more Latin than will enable him to make use of the genitive of two or three declensions in several prescriptions he may be required to write for graduation. Afterward this difficulty can be avoided by abbreviating. The knowledge he acquired at the medical school is just about the sum he retains through life, and both he and his patients are content.

But is there no difference between the life of a Newton or a Goethe and the life of a hod-carrier? Is there no such thing as a higher plane of existence? Truly there is, and that is what every individual with one spark of intelligence should strive for. The evolution of his mental forces is a duty which the physician owes both to himself and to his patients; and by the constant additions to his stock of information, the broadening of his views, the increasing the strength of his judgment, his whole life will have been spent with infinitely more pleasure to himself, with much more value to his patients, and with appreciable benefit to humanity in general.

PUBLIC SCHOOLS.

A SUBJECT that concerns the health of the majority of children in this city has of late been the theme of discussion among those interested in the system of public education. At present, there are two school sessions daily: from 9 to 12 in the morning, and from 2 to 4 in the afternoon. It has been proposed to substitute for these, one long session of five consecutive hours, to terminate at 2 p. m. All idea of shortening the sessions, is opposed by the teachers, who claim that they already have little enough time to cover the limits of the course of instruction mapped out for them. In teaching the young idea how to shoot, a prescribed amount of ammunition has to be crammed into the youthful brain, so that on a certain occasion, *i. e.*, the period of competitive examination, the charge may go off with an effective bang and flourish, regardless of physical or mental strain upon either pupil or teacher. While the one session plan has its advantages and is advocated by some, it is vetoed generally for one reason or another; but is mainly objectionable on account of its pernicious consequences upon the health of the children.

No matter how perfect the means of ventilation, the atmosphere of a school room, containing from 40

to 50 or more children for several hours, cannot fail to become impure, which has more and more effect upon all in the room, the longer they remain there. In some schools there are insufficient accommodations for a recess, and if there be any, the time allowed is too short to properly refresh the faculties and prevent exhaustion and nervousness, sure to result from such a long confinement to study and restraint upon the restless spirits of childhood.

The greater number of children attending these schools belong to families who are under the necessity of taking the principal meal of the day at the noon hour. The children coming home a couple of hours later, would miss this regular meal, and the substitution of a cold lunch, or perhaps a diet of favorite sweetmeats, or other irregular means of satisfying the appetite, would plant the seeds of indigestion, which in turn would form a foundation for other physical ills.

Many of the ailments that afflict the human frame have their origin in childhood, and are traceable to indiscretion and carelessness in those who are responsible for the care and management of the little ones. Literary education and a certain amount of social embellishment are matters of paramount importance, while health and morals are left to themselves, or fall in with the natural order of affairs, as matters of secondary consideration. Less cramming of brains, less strain upon the nervous system, more attention to physical exercise and the natural demands of the human frame, would banish bodily infirmities and establish good health, which priceless boon insures brightness of intellect, proving as a result: *mens sana in corpore sano.*

A NEW CONTRIBUTION TO OUR KNOWLEDGE OF DIPHTHERIA.

THE active researches into the etiology, pathology, and treatment of this modern scourge will, it is to be hoped, realize the ambitious expectations of those who have so zealously labored in this fruitful field. In a recent work by Dr. Bruehl, who is connected with the imperial health bureau, and which received the highest encomiums from Prof. Oertel, some points are brought out whose importance our readers will recognize. The authors call attention to the indisputable fact, proven by careful historical study, that everywhere and under all conditions the malignance of diphtheritic infection remains the same. Its deadly character is demonstrated by the official records, which show that in eight years 334,541 deaths occurred, and the remarkable fact is brought out, which is not sufficiently appreciated, that the disease is quite as prevalent elsewhere as in the larger cities.

But the most important fact which is of practical value is their claim that the etiological element for the development of predisposition to the disease, either to its contraction or further development of the infectious germs, may be sought in the frequent immediate change from an atmosphere which deprives the respiratory organs of comparatively little water, to one which abstracts from their respiratory tract a great deal of water. They deduce from this probable fact the prophylactic advice, to so construct our dwellings by proper arrangement of the heating apparatus in winter, and of the ventilation arrangements in summer, that there should be no essential difference between the moisture of the air without and within our dwellings. In addition, they recommended the hardening of children by accustoming them to exposure to all kinds of air, the improvement of waterworks, street sprinkling, draining of swamps, etc. If these observations of the author-which, it must be granted, are based upon large statistical data, are borne out by others, it will lead to the elucidation of many obscure cases of diphtheria, and probably to a successful prophylaxis.

THE CITY HEALTH.

IN the report of interments for Philadelphia, week ending December 21, we find the following:

Inflammation of the Lungs	42
Consumption " "	39
Croup	21
Inanition	19
Heart Disease	15
Typhoid Fever	15
Convulsions	14
Apoplexy	11
Diphtheria	10
Cancer	9
Debility	9
Bronchitis	9
Old age	9
Total from microbic affections	116
Tatal from all affections	336

While the number of deaths was exactly the same as the preceding week, and one less than the corresponding week of last year, it will be seen that the proportion of causal diseases has altered greatly. It seems that already the approach of influenza is making itself felt, and that those who would have died of other affections are succumbing to pulmonary diseases; to which 129 deaths are attributed. From this it appears that the true epidemic is not yet here and that the numerous catarrhal affections which now keep our physicians busy are due to local causes or are the forerunners of the true influenza. During the early part of the present week however, cases begin to appear which may be called characteristic of "la grippe;" sudden chills, with violent headache, great prostration, etc. looking very threatening, but soon subsiding.

RETENTION of amniotic remains, is treated by Eberhardt expectantly, and portions hanging from the os are removed. Those contained in the uterus are not disturbed, because the latter is free from micro-organisms. The vagina should be kept disinfected, in order to prevent decomposition of portions that may be expelled into it. If we follow Kaltenbach according to these principles, fever or other unpleasant symptoms will remain absent.

—*Zeitschr. f. Geburtshilfe u. Gynæk.*

Annotations.

PATHOLOGY AND TREATMENT OF NEPHRITIS.

IN the Italian Society for Internal Medicine Profs. Rattone and Bizzolo discussed this important theme fully. Rattone reaches the conclusion that we must substitute for the idea that nephritis always is due to a primary lesion of the kidney, the view that the latter is secondarily affected by the passage through it of substances acting as poisons and inflaming the vessels, connective tissue and epithelia. Thus the experimental and clinical conclusions of Semmola are brilliantly confirmed.

Prof. Bizzolo discussed the recently re-introduced venesection in nephritis. He regards the effect of venesection as due not to the diminution of the blood current in the inflamed surfaces, nor to the increase of the rapidity of the flow, but rather to the withdrawal of a certain quantity of toxic substances, especially in those cases in which the organism is greatly endangered by intense uræmic manifestations. It is advisable to compensate the loss of blood by transfusion of defibrinated blood or saline solutions. Diuretics are contra-indicated in some cases, but not when there is cardiac enfeeblement. In the latter digitalis, spartein and caffein are more useful. Bozzolo is an enthusiastic advocate of warm and vapor baths, but is opposed to medicinal diaphoretics; he regards pilocarpin as dangerous.

With regard to diet, his personal experience leads him not to restrict his patients to milk diet; but he lessens the consumption of meat, and forbids absolutely the use of beef, preserved meat, peptone, tea, etc., which, according to the present ideas, are true poisons to the nephritic. There are no medicinal remedies, except tannin in the hemorrhagic form, of any value.—*Int. Klin. Rundschau.*

POLITICAL MEDICINE.

OUR brethren of Minnesota do not seem to regard medicine so much as a science as a kind of political machine by which to enhance their own profits, judging from the experience of Dr. George Newgarden, recently reported in the *Press*. This gentleman, a graduate of Jefferson, applied for an examination and a license to practice to the State Board, and though he passed his examination satisfactorily, he was refused a license because he bore the diploma of a college whose course of study was three or four days short of that required by the law of Minnesota. Up to this point the State Board cannot be blamed for its action; a law that is a law should be enforced whatever its nature, and if a bad one it will soon be repealed. But it is a disgrace, if it be true, that such a law was enacted merely to compel students to attend the colleges of the State. Such an action is a direct blow to science and knocks it down to the level of the quack and pettifogger. We sincerely hope that our brethren of the West will not begin resorting to such means to boom their institutions. Let original research and a high grade of instruction be the characteristics of their colleges, and they will receive large numbers of students, though their courses of study be twice the length of those of the Eastern schools.

BROMOFORM IN WHOOPING COUGH.

THIS is recommended by Dr. Steffy in a second paper in *Wiener Med. Presse*. He has treated one hundred cases with satisfactory results. It may be best administered by dropping it into a teaspoonful of water. It falls to the bottom as a pearly mass, which is thus easily swallowed by the most refractory patients, if properly directed. For a child three to four weeks old he gives one drop; older nurslings receive three to four drops. Children from two to four years he gives four to five drops three or four times a day; increasing to six or seven drops in children seven years old. There are no unpleasant symptoms, vomiting after cough ceases gradually, the attacks are less frequent, the appetite improves and convalescence is hastened. He orders only 3.0 at a time, cautioning against exposure to sun and air. If the preparation is red, it is worthless.

CÆSAREAN SECTION VS. PERFORATION.

THIS is discussed in the *Therap. Monatshefte* by Leopold, who despite of the fact that he has lost only two cases out of twenty-five sections, advises perforation in cases in which the true conjugate measures 7.5 cm., because in twenty-two cases of the latter he has had no death.

In connection with the subject it may be mentioned that Thomson, of Dorpat, concludes from actual trials that well sterilized silk is the best material, because it is absorbed in time, while chromic acid and silk worm gut are objectionable, because of their non-absorbability, and carbolized gut because it is too quickly absorbed.

THE December number of the *Sanitarian* comes to us richly freighted with goods of value. Send for a copy. Civilization does not always go forward, but works rather in a circle; with periods of progress and intervals of backsliding. We may not for centuries see the magnificent public baths of imperial Rome reproduced, though those marvels of private luxury are fairly paralleled. And now a writer in the *Sanitarian*, after a review of the subject of the disposal of the dead, advises us to revert to the customs of the Pharaohs, and embalm them; the bodies to be preserved above ground, in a dry state, in mausoleums built for that purpose.

A NEW Journal, *Le Moniteur Medicale*, is about to appear in Paris. That it comes from the hands of M. Germain Sèe is sufficient indication of the high grade of excellence it will possess. We hope to give our readers the benefit of its contents.

NOTE.—The "Manual of Treatment, by Taylor and Waugh," is withdrawn from our offers for the present, the edition having been exhausted. It will be at least six months before a second edition can be prepared.

Letters to the Editor.

A CORRESPONDENT inquires if there is a man of ability and energy who would care to establish a sanitarium. He has a friend who is a physician living on the Erie sixty miles from New York City. His home is a fine three-story brick, fifty by sixty. There is one acre of ground, well shaded in summer, and altogether it is a beautiful and well-kept property. He would sell or rent the same for a sanitarium. The doctor himself, who is sixty-two years of age, can and would render valuable service in the management of such an institution. Our correspondent considers it a fine opening.

Society Notes.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON ORTHOPÆDIC SURGERY.

Stated Meeting, October 18th, 1889.

A. B. JUDSON, M.D., Chairman.

RACHITIC PSEUDO-PARALYSIS.

THE paper of the evening was read by Dr. H. W. Berg, who stated that in this affection the rickety child from two to five years old is unable to walk, and in some cases he cannot stand or even sit. The disability is not the result of nervous lesion, but rather the result of muscular weakness, pain in the muscles and in the bones at the points of muscular attachment, flaccidity of the ligaments, and softness of the bony levers. Such a child wishes to be let alone. He instinctively prefers to keep quiet. This condition may be distinguished from infantile paralysis by the absence of local atrophy and cold; and real paralysis, not so readily, however, from post-diphtheritic paralysis where the differential diagnosis will rest on the preceding occurrence of diphtheria, the recent origin of paralysis, and, above all, on the difficulty of swallowing and speaking dependent on involvement of naso-pharyngeal and laryngeal muscles. Spastic paralysis, even when mild, has an exalted muscular activity which serves to distinguish it from rachitic pseudo-paralysis; and the paraplegia of Pott's disease cannot be mistaken if the kyphosis is obvious. The prognosis is uniformly favorable. These are the cases which give such good results after indiscriminate circumcision. The object of treatment should be to counteract the effect of rachitic malnutrition. These children should have a great deal of milk; cod liver oil should be given unmixed; and phosphorus in the following prescription:

℞.—Phosphori . . . . . gr. j.
Alcohol. absolut . . . . . ♏ cccl.
Spt. menth. pip . . . . . ♏ x.
Glycerinæ . . . . . oz. ij.
M. et Sig.—Six minims t.i.d. to be increased one drop weekly until ten drops are given.

Dr. W. L. CARR had seen a number of cases in which a striking lack of muscular power was symptomatic of rickets, although bone changes were not obvious. A number of these children had been fed at the table or on patented foods. Proper attention to diet soon brings about a restoration of muscular powers without tonics.

DR. R. J. DEVLIN recalled well marked cases of this affection in children who had been exclusively fed on milk from a healthy mother.

NERVOUS SYMPTOMS PRODUCED BY PHIMOSIS.

DR. T. H. HOLGATE said that in his experience with non-rickety children, the relief of preputial irritation by discriminating operative interference had removed serious nervous troubles. In one case, which had been presented to the Academy, inability to walk or stand had been relieved in this way in a child who was entirely free from evidences of rickets.

DR. R. H. SAYRE related a similar case of a boy, who from some central lesion, had not walked for some years. After partial circumcision he could walk with the aid of two canes. A trouble of twelve years' standing had thus been relieved in six weeks.

DR. BERG closed the discussion. He agreed with Dr. Carr in thinking that rachitic inability to walk is sometimes present without the usual rachitic deformities. He recognized the fact that urinary troubles occur as the result of contracted prepuce, but he had never seen a case of lesions of the nervous centres cured by circumcision. He recalled a case of difficult micturition and inability to walk in a rickety child whose phimosis had not been relieved because the operation had been refused. The difficulty in micturition persisted, but the child walked within eight weeks after being put on proper diet.

EXCISION OF THE HIP JOINT.

DR. R. H. SAYRE presented a little boy on whom Dr. L. H. Sayre had operated by excision of the hip joint. About a year ago the patient had presented himself with hip badly deformed from long standing disease. The thigh was flexed on the trunk at a right-angle and abducted. A deep abcess was opened behind the trochanter, and the acetabulum and femoral head were found to be badly eroded. The femur was divided above the lesser trochanter, at right-angles with the axis of the shaft, and the deformity was thus reduced by excision instead of by simple tenotomy, which had been proposed at first. The wound was stuffed with iodoform gauze, and after two months of the wire cuirass, a long traction splint was applied, and the boy took a long journey to his home. At the present time there is no abduction, and but a trace of flexion with some motion in the joint.

TREATMENT OF ABSCESSES.

DR. JOHN RIDLON asked whether an operation would have been advised for the abscess alone. He had found that many abscesses are certain to disappear when the hip is properly treated mechanically.

DR. SAYRE said that as the abscess was causing but little disturbance, he would have postponed operating on it if the child could have been kept under observation.

Dr. Judson thought that opening an abscess, if done at all, should, as a rule, be followed by excision—as in the case related by Dr. Sayre—on the ground that the presence of diseased bone is a greater evil than the presence of pus. He had seen no bad results follow letting the abscesses alone.

Dr. A. M. Phelps said that there were some cases of abscess which he would probably not open at once, but he believed the operation perfectly harmless, and desired to speak emphatically against the opinion that it is a dreadful and a dangerous thing to open these abscesses.

Dr. H. L. Taylor thought that if rest and protection are secured for the joint, the occurrence of abscesses is not of serious import. The aspirator had failed in his hands, apparently because it leaves shreds of necrotic tissue, which prevent the abscess from closing. It seems wise, in most cases, to open freely, clean out easily-removable débris, and close the wound. If sinuses remain, injections with a saturated solution of iodoform in ether will sometimes cause them to close.

Dr. L. A. Sayre said that on the principle that an empty house is better than a bad tenant, he always evacuates an abscess as soon as found, and by doing this antiseptically, and securing thorough drainage, there is no danger of bad results.

Dr. R. T. Morris said his usual custom is to open these abscesses at once, washing out with peroxide of hydrogen, removing débris, and establishing drainage. He related a recent case in which this procedure, followed by traction in the line of the deformity, had secured a good result. He had recently performed excision in another case, in which disease of the acetabulum and femur had been produced by the application by the physician in attendance of traction in a straight line, according to Thomas' method. In excising the hip, he usually makes a section through the great trochanter, in such a way as to allow the lesser trochanter to go into the acetabulum, and so prevent the formation of a flail joint.

THOMAS' SPLINT.

Dr. Ridlon did not think Thomas, of Liverpool, made traction in any line.

Dr. Phelps said that Mr. Thomas would treat a case when the leg is flexed at right angles, by lashing the patient to the splint, and then with his wrench bending the splint down as nearly as possible to a straight line. That is a form of traction which produces great intra-articular pressure, and would, if continued for any length of time, produce destruction of the joint.

Dr. Ridlon said that he had used Thomas' hip splint in some twelve or fifteen cases with great satisfaction. He found it cheap and easily applied. It had not caused destruction of tissue, but, on the contrary, had relieved symptoms and promoted recovery.

Dr. L. A. Sayre said it seemed as if the profession were determined to misunderstand him, for he had endeavored for years past to make clear what he meant by traction in the line of the deformed limb: it is to make traction in such a way as to separate slightly the bone from the base of the acetabulum, and so prevent pressure, gradually changing the line of traction until the limb is brought parallel with the other limb, and then apply the splint; whereas, if one employed leverage, as Thomas does, this pressure in the joint is only increased. Not until the limb is in proper position can the splint be applied to advantage. One objection to Thomas' splint is that there is no traction for overcoming muscular rigidity, and hence, it seems to be fixation only, and as such does not compare in point of efficiency with a properly-applied plaster of Paris splint; for here the weight of the limb will produce some traction, and the plaster of Paris gives the necessary fixation. Another objection is that the patients wearing Thomas' splint cannot sit down, whereas, with a properly-applied splint, they can sit down with great comfort.

THE QUESTION OF EXCISION.

Dr. R. H. Sayre said that in the case presented, the original intention had been simply to open and drain the abscess; but the diseased condition of the bones necessitated excision. As regards the conditions under which he would advise excision, if the leg were straight and the abscess causing but little disturbance, he would postpone the operation, provided the patient could be kept under observation; but if the latter condition could not be secured, he would be disposed to remove whatever disease already existed rather than allow the case to go from under observation with the disease ready to extend at any time.

Dr. Berg thought the good condition of the patient in the present case justified operative procedure for the correction of deformity.

Dr. Taylor thought that excision might be required in neglected cases, of which there probably always will be a considerable number; but the operation should be looked upon rather as treatment of the results of neglect than as treatment for hip disease.

Dr. Phelps practiced excision by an open wound, leaving the periosteum to reproduce bone. The German surgeons remove the periosteum and capsule, and try to secure union by the first intention. Their results are shortening, flail joints, and relapses in a large per cent. of cases. He related two recent cases of excision in patients thirty four and twenty-three years of age. In these cases, the femoral head was destroyed, and the acetabulum extensively diseased, a condition in which removal of the disease is the most rational treatment. In one of the cases the head was found separate from the shaft. He had frequently found this condition, and believed that the head lying loose in the joint cavity is to be considered as a foreign body. It is better to remove it than to leave it to undergo decomposition and lead to septicæmia and amyloid disease. A more useful limb is left if the exsection includes the trochanter. In general, he thought excision under the age of ten is a calamity. In the case presented, however, he thought the result was good, as extreme deformity had been corrected.

Dr. Judson thought that in excision we have no certainty of removing, together with the diseased

bone, those portions which contain latent foci. He had found no method of determining whether the focus which has burst into inflammation is the only outbreak to be feared, or whether it is to be followed by others. In some patients, a single abscess closes the morbid process; in others, one abscess follows another, showing that osteitis is lighted up successively in the neck, the head, the shaft, and the bones of the pelvis. An excision may fortunately remove all that is diseased, with a good immediate result; or it may leave dormant foci, which come into activity one after another, and lead to a tedious and unfavorable result. Ultimate good results are obtained in these difficult cases by management with the hip splint, and without excision.

THE POLYCLINIC MEDICAL SOCIETY.

THE Polyclinic Medical Society gives, under its auspices, a lecture, or holds a meeting of its Therapeutical Section, every Tuesday evening, at 8 o'clock, at the College building, N. W. corner Broad and Lombard streets, during the season. The lectures pertain to subjects of a clinical and scientific character, and its monthly meetings are devoted to the physiological and practical investigation of therapeutic agents. The whole course is free to members of the profession and to medical students. The following lectures and meetings are announced for 1890:

January 7. Dr. Alexander MacCoy, The Clinical Features of Tuberculosis of the Larynx.

January 14. Dr. B. F. Baer, Abdominal Surgery.

January 21. Dr. Thomas G. Morton, Modern Treatment of Club-foot

January 28. Meeting of Therapeutical Section.

February 4. Dr. Edward P. Davis, Use of the Obstetric Forceps.

February 11. Dr. John B. Roberts, The Anatomy of Facial Expression.

February 18. Dr. J. C. Henry Simes, Prostatorrhœa.

February 25. Meeting of Therapeutical Section.

March 4. Dr. R. W. Seiss, Inflammation of the Eustachian Tube.

Cincinnati Letter.

IN rheumatism, Prof. J. T. Whittaker recommends the salicylate of soda to be given in doses of seven and one-half grains every three hours until the pain disappears. He lays great stress on the frequent repetition of the dose. After the pain has ceased, the dose should become less frequent.

A woman came under the care of Dr. Joseph Ransohoff at the Cincinnati Hospital, recently, who was suffering from constipation, due to the taking of laudanum in large and frequently repeated doses. Some fourteen months since she had, on account of stricture of the rectum, been operated upon, and an artificial anus made by abdominal colotomy, in our neighbort ing city of Louisville. The operation left behind i- a very successful substitute for the old anus, a sphincter being formed, and, excepting under the influence of opium taken for the relief of the pain, her actions were good. There was, however, a considerable raw surface about the site of the operation. Dr. Ransohoff determinded to try to open up nature's old way, which he did before the class in the amphitheatre. The lower part of the rectum was excised, and the gut brought down and sutured to the anus in front and at the sides; but not in the rear. The object in leaving it open in the rear was to obviate the occurrence of abscess, as it is through this accident that about one-half of the cases of excision meet with their deaths. The cavity of the gut was packed with iodoform gauze. The patient suffered considerable pain after the operation, but is at this writing on a fair way to recovery. The doctor in his remarks before the class said that this was, as far as he knew, only the second operation of this kind where there was present an artificial anus.

Dr. H. L. Taylor, editor of the Cincinnati *Medical Journal*, is in the South for the benefit of his health.

The improvements at the Cincinnati Hospital are about completed and make a very fine showing. The arrangements for the reception of patients, the bathing of the same, and transferring to the various wards, are excellent. The post mortem room is another feature which is hard to improve. Arrangements are being completed by which the patrol wagon on entering the hospital yard will strike a bar in the ground, which will pull a trigger, open the gates into the hospital, ring a bell in the attendant's room and turn on the electric light. The patrol wagon now goes inside of the hospital, and does not unload its freight under the gaze of the gaping crowd as formerly. On motion of Dr. C. L. Armstrong at the last meeting of the board of trustees of the hospital, a chair of Laryngology and Rhinology was added. Motions to establish chairs of Photography and Neurology were laid over, and a motion to establish a chair of Orthopedic Surgery was lost.

Emmett's operation was performed by Dr. T. A. Reamy, Professor of Clinical Gynecology in the Medical College of Ohio, and Gynecologist to the Good Samaritan and Cincinnati Hospitals, before the class at the Good Samaritan Hospital recently. He emphasized the fact that he did not insert first the stitch nearest the apex of the denudation, but the second and third from the apex. His experience had been that it was very difficult to tell just how much tissue you were taking, and just how perfect the coaptation would be on inserting the highest stitch first. The doctor after a thorough trial of all kinds of sutures has settled down on catgut in this operation. He advises that a suture large enough to fill the entire tract of the needle be chosen. He advises the cutting of the thread long, as a short stubby suture is more apt to get between the surfaces which are in coaptation, and prevent their union.

The Medical Treatment of Dysmenorrhœa was the subject of a paper before the last meeting of the Cincinnati Obstetrical Society, by Dr. E. W. Mitchell, Professor of Internal Medicine in the Cincinnati Policlynic. Remedial measures he divided into those of relief and those of cure. Of the former, opiates are the most powerful for relief and for evil. They should

be avoided. Chloral, if used at all, should be with caution, because of the danger of forming the chloral habit. The prolonged use of the bromides in anæmic subjects has a depressing effect on the general health, and under these circumstance is not good treatment. For the relief of the paroxyms they are of value, and may, sometimes, as in spasmodic cases, be advantageously combined with belladonna or hyoscyamus. With cannabis Indica the writer has often obtained immediate relief, especially so in cases where the flow is free. Antipyrin is a valuable addition to our means of relieving pain. Tincture of cimicifuga and pulsatilla have both been found to give relief in some cases. Oxalate of cerium in six-grain doses has been recently recommended in fleshy robust women with scanty flow. Hygienic treatment is among the best of all curative treatments. Nutrition, exercise, healthful mental and moral surroundings are of the utmost importance. Young girls must receive special attention with regard to these matters, and all undue drains upon their vital forces, as to close confinement in school, at music or art lessons, late hours, and the dissipation of society must be discontinued. Local treatment is seldom necessary. The trouble in these cases is lack of development of the utero-ovarian system. The demands of our modern education and the excitements of "society" keep the demands of the brain and nervous system for nutriment so active, that there has not been sufficient to complete the growth of the sexual system. She now comes to perform an adult function with an infantile organ. The effort is imperfect and painful. The reproductive organs must be given a chance to catch up with the rest of the system in its development. Cases where neurasthenia or mal-nutrition are prominent are best treated by a course of "rest cure," seclusion, milk diet, massage and electricity. The existence of anæmia usually indicate iron, and arsenic is valuable as a tonic. Electricity, both general and local, has rendered him good service. Apiol and manganese he believed to have some specific influence upon the utero-ovarian system. The bin-oxide is probably quite as efficacious as the permanganate and, being easier to give, is preferred. Of the eight cases reported, apiol, bin-oxide of maganese, galvanism and iron had given relief, in cases uncomplicated with appreciable pelvic disease. When constitutional measures do not relieve, examination and dilatation, or other surgical measures indicated, should be made. The general practitioner is perhaps as prone to persist in medical treatment alone, when surgery is needed, as are some specialists to undue haste to examine and operate.

At the Cincinnati Hospital the custom in the obstetric ward is to give a vaginal douche of bichloride of mercury, 1–4,000, at the commencement of labor, and one after the delivery of the placenta. Unless symptoms demand it this is not repeated any more. It is customary to give a half drachm of fluid extract of ergot after the delivery of the placenta.

The treatment of threatened abortion is becoming a matter of considerable importance, partially on account of the change in the mode of living of the women of the present day, and partially because of the alarming frequency of criminal abortion. An interesting case is reported by Dr. E. S. McKee, of Cincinnati, which is worthy of mention. Was called hastily to see a woman suffering from uterine cramps. She was found in the seventh month of pregnancy and seriously threatened with abortion. Dioviburnia of the Dios Chemical Co., St. Louis, was prescribed in dessertspoonful doses four times a day. The pains subsided and the threatened abortion passed off. About one month later was called again and found the same condition of affairs, except that the woman was now in the eighth month of labor. She begged for that medicine which had relieved her so much before, and was again given the Dioviburnia, in the same dose. This threatened miscarriage also passed by, and the woman was in due time delivered of a fine, healthy child. After the delivery was safely over she confessed to her attendant that she had on both these occasions made desperate efforts to bring on a miscarriage. The remedy has done quite well in other cases, but this is probably the one most marked. It merits further trial.

The obstetric clinic of the Medical College of Ohio, which is now under the efficient management of Dr. E. G. Zinke, is assuming proportions thought impossible in modest America. Dr. E. G. Zinke's predecessors worked with little success, but this year already thirteen patients have been delivered before the students, and a number of others are waiting. This is a very important clinic, and the most difficult of all for which to find material.

The appetite for gynecological surgery in Cincinnati has become so whetted that one gynecologist complains that another operator followed a case of his to her hotel on her arrival in the city, and by fair words and an offer to do the work free, induced the patient to go under his care; this, too, after gynecologist number one had examined the patient, agreed on the fee of two hundred and twenty-five dollars and closed the bargain.

Another gynecologist complains that he made a like bargain with a patient for a like sum, but she was enticed into a neighboring city where the operation was done for one hundred dollars. Such methods of doing business were not taught us by our fathers, and do not redound to the credit of the profession.

Hospitalismus is epidemic in Cincinnati. The mania for starting hospitals in the last few years has become alarming. So far as memory serves us, the following are comparatively new, the list being quiet complete, though a few may have escaped: Reamy's Hospital, Reed's Hospital, Rickett's Hospital, Lodge Street Hospital, United States Marine Hospital, German Protestant Hospital, Christ's Hospital, Ohio Hospital for Women and Children, Ohio State Hospital for Women, Hall's Hospital, Free Hospital for Women. If this does not look like bidding for paupers, what does it resemble? True some of these are of a private nature.

The removal of the second ovary is frequently a question of no little delicacy to decide. A case of this kind of peculiar interest was one which was operated on by Dr. T. A. Reamy, of Cincinnati, in his private hospital. True, it is becoming much more

common now than formerly, to perform the ovariotomia duplex, but the fact that the double operation has now become but little if any more dangerous, intrinsically, than the single one, does not relieve us of the moral side of the question.

A matter of no little difficulty is it to tell on inspection, whether the second ovary shall be removed or not in a given case. It is not always easy to decide, whether or not we have to deal with a beginning neoplasm which renders extirpation advisable, or whether there is merely an unusual development of follicles on account of which the organ may be enlarged two or three-fold. If there is no doubt of the presence of a neoplasm, the second ovary is as a rule to be extirpated. This, however, is only a plain statement, and is subject to many modifying circumstances. For instance in the case of Dr. Reamy just mentioned, the lady was young, intelligent and wealthy. She was engaged to be married. She had been suffering intolerable pain for a long time, not only during the menstrual, but also the intra-menstrual period. As all the pain was in the left ovarian region, the promise was made the patient that the right ovary should not be disturbed, unless positive evidence of disease presented on exposure. Yet her hearty consent was given to remove it if necessary. While no disease was found demanding the taking out of the ovary, yet to make sure of a thorough cure the temptation was to remove. The few moments parley was fraught with importance. Dr. Reamy asked the advice of the gentlemen present. One would remove it, another would not remove it; the latter gentleman the proud father of three fine boys. Still another inclined to a double operation, fearing a return of pains. Dr. Reamy, after a few moments' careful consideration, allowed the ovary to remain and the woman the right to become a mother as well as a wife.

The case of Sir Spencer Wells is well known. He was in doubt whether to remove both ovaries where one had two cysts, the size of a cherry. The ovary was left undisturbed, and the patient married, bearing four children.

Schroeder, in cases where a new growth was recognizable, and ovulation very desirable, resected the second ovary, allowing healthy tissue to remain, and closed the wound with a few stitches.

It is probably not the removal of the second ovary, which makes the operation any more difficult or dangerous, but rather the fact that the most unfavorable tumors, from an operative standpoint, are most frequently bilateral. If the desire is to abolish ovulation and menstruation, as for instance in fibroids accompanied by hemorrhage, then the second ovary should be removed, even though healthy. In the case of Dr. Reamy, just referred to, the left ovary and tube was removed; the tube was not occluded, but thickened and congested. The fimbriated extremity was adherent to the pelvic peritoneum, and the ovary was considerably atrophied; the cortex of the ovary was much thickened and unusually firm. This condition was so marked that Dr. Reamy thought it would offer reasonable explanation of the unbearable dysmenorrhœa. Interference with the discharge of the Graafian follicle, consequent upon the change, he had often verified. He stated that the late Dr. James B. Hunter, of New York, had emphasized this view in a paper read before the American Gynæcological Society, in 1886. The patient made an excellent recovery.

Dr. Reamy has had a case of laparotomy at his clinic at the Good Samaritan Hospital, before the students of the Medical College of Ohio, every clinic for four successive clinics, a fact which he says has not been equalled by any other college in America.

Book Reviews.

Transactions of the Medical and Chirurgical Faculty of the State of Maryland at its Ninety-first Annual Session, held at Baltimore, Md., April, 1889. Pp. 264. JOHN B. KURTZ, Baltimore, 1889.

Glancing through these transactions, we are pleased to note the general practical character of the papers. The address by the president, John Morris, M. D., dealt with the all-absorbing question of Crime at the present day. Dr. William Osler delivered the annual address, taking for his theme the License to Practise. Two of the papers upon surgery were in connection with affections of the nervous system. Dr. Canfield read the paper upon practice, taking for his subject the Relations of Dusty Occupations to Pulmonary Phthisis. Obstetrics and gynæcology were poorly represented, only Dr. Neale having a new obstetrical forceps to show. Hydrophobia was discussed by Dr. William H. Welch; hypnotics and antipyretics, by Dr. Whitfield Winsey; aphasia, by Dr. Samuel J. Fort; and some experiments with ethylic alcohol, by Dr. John C. Hemmeter. Dr. George H. Rohé explained a painless and efficient method of extirpating vascular and pigmented nævi; and Dr. A. K. Bond related a case of aneurism of the abdominal aorta, bursting into the pleural cavity. Such are the more important papers which appear in the above transactions. The only criticism to be made in regard to most of them, is the notable absence of personal experience and the relation of positive facts. Scientific discussions are without doubt of immense value, but their value is still more enhanced when they are based upon original investigation.

Pamphlets.

Misplacements of the Uterus; history of cases showing how in many instances they are produced; the accompanying conditions; microscopical examinations. By Mary A. Dixon Jones, M.D., Brooklyn, N. Y. Pp. 32. Reprint from the Pittsburgh *Medical Review*, October, 1889.

The Mode of Entrance of the Bacillus Tuberculosis into the System. By Lawrence F. Flick, M.D. Pp 9. Reprint from the TIMES AND REGISTER, October 19, 1889. Medical Press Co., Limited, Philadelphia, 1889.

How to take Care of the Lungs. By Lawrence F. Flick, M. D. Paper read before the Alumni Association of the Philadelphia College of Pharmacy at its Fifth Social Meeting, February 12, 1889. Pp. 14. Burk and McFetridge, printers, Philadelphia, 1889.

THE Belgians drink more spirituous liquors than any people in Europe.

The Medical Digest.

MECHANICAL treatment of erysipelas was practised in twenty-four cases by Professor Woelfler, with success in twenty-one cases, chiefly of the face and body. Adhesive plaster was carefully applied in strips.—*Wien. Klin. Wochensch.*

SUGAR in the urine of puerperal women was found in four-fifths of all cases examined by Dr. Ney, who regards it as a physiological condition. It begins with the accession of the lacteal secretion, and is more pronounced in those women in whom the latter is more abundant. Mastitis and fissures which result in stasis of the milk, favor the appearance of sugar in the urine. There is none present in women who have no supply of milk. Infants thrive best when nursed by women who have the most sugar in their urine, because in these the lacteal secretion is most abundant and nutritious. Hofmeister had shown that the sugar found in the urine of puerperæ was milk sugar, not grape sugar. It is carried into the blood by transudation from overfilled milk tubes, and excreted by the kidneys.—*Arch. f. Gynæk.*

SALINE HYPODERMIC INJECTIONS IN POST-PARTUM HEMORRHAGE.—In the Dresden Lying-in Hospital the plan of introducing a large quantity of a solution of common salt under the skin has been very successfully employed in several severe cases of post-partum hemorrhage. The solution is of the strength of 0.6 per cent., and the quantity injected is a liter, or a little under a quart. The spots selected for the injection are the infra-clavicular and the inter-scapular regions. During the progress of the operation the swelling produced under the skin must be manipulated by a sort of shampooing movement so as to disperse the liquids as much as possible. The water with which the solution is made must be sterilized or well boiled. The advantages of the plan are that it can be easily carried out by any medical man, as it is far less difficult than transfusion, besides which it is not so dangerous. Dr. Münchmeyer considers the plan so suitable for private midwifery practice that he suggests a little apparatus, which is made on purpose for it, that should always be carried in the obstetric bag, together with the proper quantity of common salt. Boiled water can always be procured, and this, when cooled down to the temperature of the body, 98.6° F., will do very well, though in hospital clinic he employs a more strictly sterilized solution.

—*Lancet.*

OPERATION AND PROGNOSIS OF LINGUAL CANCER.—During the past thirteen years ninety-one extirpations of the tongue for cancer have been done in Volkmann's clinic. In fifty-six partial excisions the mortality was 0 per cent., in thirty-five complete ones 5.7 per cent. These favorable results induced Volkmann to publish the technique and after-treatment he pursues.

Volkmann does not tie the lingual artery, nor do tracheotomy. When it is possible to bring the tongue with its tumor in front of the teeth, he excises through the mouth; in the severe cases Langenbeck's method of temporary section of the lower maxilla is practised by means of an ordinary saw. The palato-glossal arch is severed each time, and later a drainage tube is put into the tonsil-niche. After thorough extirpation, the wound is united by bringing mucous membranes as near as possible together. The maxilla is united by silver wire, and produces either bony or ligamentous (useful) union; sometimes partial necrosis. The œsophageal tube is not used. Operation close to the epiglottis is declined. After the thirty-two severe cases, the average duration of life was twelve months; one man lived over six years. Among the fifty six partial excisions seven remain alive; the shortest period of survival, eight months; the longest six years.—*Krause, Ctbl. f. Chirurgie.*

THE SURGICAL TREATMENT OF VOLVULUS.—Dr. Nicholas Senn, in an elaborate article on this subject, has deduced the following conclusions:

1. The predisposing causes of volvulus are either congenital or acquired, and consist in elongation of certain segments of the intestine, abnormal length of mesentery and adhesions.

2. Irregular distribution of intestinal contents and violent peristalsis are the most important exciting causes.

3. Volvulus is most frequently met at the sigmoid flexure and the lower portion of the ileum.

4. Secondary volvulus on the proximal side of other forms of intestinal obstruction is not a rare occurrence; it is also frequently developed during an attack of peritonitis.

5. As a rule, the symptoms are more acute and intense if the volvulus is located above the ileo-cæcal region.

6. Vomiting in cases of volvulus of the sigmoid flexure is not a constant symptom.

7. The most important physical sign of volvulus is a circumscribed area of tympanites, which corresponds to the location of the volvulus; but this sign is only of value before general tympanites has set in, and, therefore, enables the surgeon in many cases to make an early and positive diagnosis.

8. All cases of volvulus should be treated by laparotomy, if reposition cannot be accomplished by rectal insufflation of hydrogen gas.

9. Reposition should not be attempted without evisceration.

10. Evacuation of intestinal contents by a free incision should be practised in every case where general distension of the intestines is present.

11. Enterectomy becomes necessary if any considerable portion of the intestinal wall has become gangrenous.

12. Irreducible volvulus should be treated by establishing intestinal anastomosis, with permanent exclusion of the seat of obstruction from the active fæcal circulation.

13. Recurrence of volvulus can and should be guarded against by shortening the mesentery, by folding it upon itself parallel to the long axis of the bowel and suturing the apex of the fold to the root of the mesentery.—*Medical News.*

Medical News and Miscellany

TYPHOID malaria is prevalent in Jersey City.

LUDLOW, Ill., has several cases of diphtheria.

ANOTHER Yale student has died of typhoid fever.

Dr. W. E. McChesney has removed to Tonawando, N. Y.

A new medical society has been organized in Pittsburgh.

THE Edinburgh School for Medicine has twenty-two women students.

ST. LOUIS physicians are making experiments to test hypnotic influence.

CELERY has been used by the Egyptians as a specific for sea-sickness.

THE *American Analyst* says there is an alarming increase of alcoholism in Europe.

A NEWTON, L. I., butcher furnishes the New York people with sausages made of horse flesh.

As a substitute for quinine the *American Garden* recommends onions for the cure of malaria.

FOURTEEN per cent. of the lunatics under treatment in France owe their insanity to alcoholism.

EDMUND YATES states that twenty-eight officers of the German army committed suicide in one month.

ANOTHER victim of cigarette smoking; this time in Connecticut, where there is an existing cigarette law.

THROAT specialists say that American tobacco is more irritating to the throat than the high grades of Turkish tobacco.

IN Iowa even a prescription fails to obtain liquor for those who ever use it as a beverage. Rattlesnakes are dead stock there.

IN these days of microbes what dire calamities lie in wait to slaughter the innocent gamin as he smokes his prized cigar stump.

THE new City Hospital at Baltimore, under the care of the Sisters of Mercy, was opened on Monday with impressive ceremonies.

THE quantity of artificial infant food annually consumed in the United States amounts in value to from $8,000,000 to $10,000,000.

THE low rates of mortality of the past few seasons show that an increased unhealthfulness does not result from humidity of the atmosphere.

NEW YORK recently has had the lowest rate of mortality that has been reached in the period covered by the annals of the Health Department.

LONDON HOSPITAL cautions people against going too long without food, and allowing the period of hunger to pass, and fatigue and depression to set in, when the desire for food is gone and with it the ability to properly digest a meal.

THE Association of American Anatomists meets at the University of Pennsylvania on December 26, 27, and 28, under the Presidency of Dr. Leidy.

THE *London Hospital* urges the necessity of sufficient sleep for the brain-worker. So does the interested party. The trouble is to get the sleep.

IT IS said that children swap chewing gum from mouth to mouth. Diphtheria was communicated in this way to a number of playmates recently.

THE leaders of a gang of opium smugglers that have infested Puget Sound, were arrested with two thousand dollars worth of opium in their possession.

DR. SARGEANT, of Harvard College, says that those who have been most successful in heavy gymnastics are also subject to nervous complaints.

To break up a cold and prevent a cough, the *British Medical Journal* prescribes twenty grains of salicylic acid in liq. ammon. acet. three or four times a day.

"MORTON'S TOE" is a disease that comes from wearing tight shoes, where the end of one of the nerves of the foot is squeezed between two of the toes.

SAYS a journalist—our grandfather's clock may do for us now, but our grandfather's physician never would in the world, and our grandfather's surgeon still less.

THE split in the St. Louis Medical Society appears to be irreparable, the faction which imported political methods being left quietly to enjoy them alone by the other members.

LUMBAGO.—A valuable internal remedy:

℞.—Ext. Cimicifugæ fl . . . . . 1 oz.
Celerina (Rio) . . . . . 7 oz.
M. Sig.—Teaspoonful every four hours.

THE Brooklyn Board of Health has caused the arrest of three faith curists who attended a mother and child sick with diphtheria, to the exclusion of medical treatment.

If the European influenza is not a forerunner of cholera, it may be followed by an epidemic of the Brazilian type, that, like itself, will first affect the St. Petersburg court.

CINCINNATI owns two babies, born within a week of each other, provided with well formed teeth. N.B.—A wise provision of nature in preparing them for tough Cincinnati beefsteaks.

CORRECTION.—In a letter received from Dr. A. M. Fernandez, he requests us to make the following corrections in a report recently published in this journal: "I did not give morphine to my patient; I did not call nature 'Dame nature;' the 'fourthly,' as he calls it, was born before Dr. Wilson's arrival; the figure indicating the circumference of the head of one of the fœtuses is wrong; I never said 'we succeeded perfectly,' nor 'that there is a similarity between my case and the bond of union in the celebrated Siamese twins.'"

PROF. WESTPHAL, of Berlin, a brilliant lecturer and distinguished authority on mental disease, has himself fallen a victim to the disease he so successfully combated in others.

A YOUNG physician who desires a location can hear of a good one by addressing this office. The applicant must be a practical temperance man, though not necessarily a teetotaler.

THE French Academy of Medicine has proved that of all the essences that can be used in the preparation of absinthe, the essence of wormwood is the most toxic and consequently the most dangerous.

THE Isle of Man is particularly free from consumption and kindred ailments, although the fishermen's huts have earth floors, which in rainy weather become mud and seem peculiarly contributive to lung diseases.

THE search for smuggled opium carried on in San Francisco is a failure, owing to precautions taken by the smugglers, who have ceased operations, the supply of opium stored being sufficient for a year without occasioning any embarrassment in the trade.

A CANADIAN practitioner, through absent-mindedness, prescribed bisulphate of morphine instead of quinine. The drug clerk, perceiving an error, substituted sulphate of morphine. The result was fatal, and a double suit is pending to settle the question of who caused the death.

A Plymouth, Pa., father, who lost two children by the fever epidemic of 1885, brought suit against the Plymouth Water Company for providing impure water, thereby causing disease and death; but the case was non-suited, evidence being brought to prove that the nurse contaminated the water.

THE mother of a medical student in Vienna who was afflicted with blood-poisoning, had all knowledge of her suffering kept from her son lest it injures his chances of success, and died from a too long delayed amputation on the same day that he passed with honor his examination for a doctor's degree.

DR. WHARTON SINKLER was elected President of the Nurses' Protective Association. The object is to give sick benefits to all nurses who are indisposed, and to afford them protection—though it is not stated from what. If it be from the fatal malady which deprives us of our best nurses—matrimony—the Association has our hearty support.

A GERMAN railway engineer, whose presence of mind saved a disastrous collision, has since become a wreck from the effects of the great nervous strain. His legs are benumbed, there is a diminution of nervous sensibility over the entire body, and his digestion and memory are impaired. Besides this he is afflicted with an inability to sleep.

THE Open Court Publishing Company, of 169–175 La Salle Street, Chicago, Ill., announces the immediate appearance of the authorized translation of M. Th. Ribot's "Psychology of Attention." The monograph of M. Ribot, who is now Professor of Experimental and Comparative Psychology at the College de France, and Editor of the *Revue Philosophique*, has been characterized by a prominent French critic as the most important production of the French philosophical press for the present year.

ABOUT one hundred professional nurses from the hospitals of the city met in the lecture-room of the College of Physicians, to form a beneficial association for members of their profession. Dr. Wharton S. Sinkler, of the Philadelphia Hospital, presided, and brought forward several schemes for paying sickness and death benefits to the members of the new society. A committee consisting of Henry Hodgeson, Max Neuman, Miss S. G. Haydock, of the Woman's Hospital; Miss I. G. Shaeffer and Miss Josephine Durkee, of Blockley Hospital, was appointed to examine the constitutions proposed, and to submit reports on them at the next meeting, which will be held on December 17, at the College.

THOSE who claim to see grave dangers to the community in hypnotism may thank us for giving a remarkable proof of the correctness of their assumption. It can no longer be doubted that one person of powerful intellect can obtain such a control over another individual as to compel the latter to do certain acts irresistibly and unconsciously. Thus, we have hypnotized the editor of the Texas *Health Journal*, and compelled him to republish, word for word, a review, without credit, of Sajous's Annual, which appeared some time ago in THE TIMES AND REGISTER. Unfortunately, the demonstration is incomplete, as we forgot to hypnotize the printer, and the result is a racy originality as to spelling, which is all his own.

To Contributors and Correspondents.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Changes in the Medical Corps of the United States Navy for the week ending December 21, 1889.

KITE, J. W., Assistant-Surgeon. Promoted to be a Passed Assistant-Surgeon.

STONE, E. P., Assistant-Surgeon. Promoted to be a Passed Assistant-Surgeon.

NORTON, O. D., Assistant-Surgeon. Promoted to be a Passed Assistant-Surgeon.

HENRY, CHARLES P., Assistant-Surgeon. Placed on the Retired List.

PICKERELL, GEO. McC., Assistant-Surgeon. Ordered to Navy Yard, Washington, D. C., for temporary duty.

Medical Index.

A weekly list of the more important and practical articles appearing in the contemporary foreign and domestic medical journals.

Acute pelvic inflammation, the abortive treatment of, Hardon. Atl. Med. and Surg. Jour., Dec., 1889.
Aneurism in each popliteal space, Michael. Maryland Med. Jour., Nov. 23, 1889.
Azione biologica della bebirina, Weinert. Giornale Medico, Ottobre, 1889.
Brain specimens, chiefly illustrating localization, Mills. Univ. Med. Mag., Nov., 1889.
Cocaine in labor, Wagner. Therap. Gaz.. Nov. 15, 1889.
Cystic tumor of conjunctiva produced by striking the eye with bristles of a hair brush, Phillips. Atl. Med. and Surg. Jour., Dec. 1, 1889.
Catarrhal neuralgia. Med. Rec., Dec. 7, 1889.
Creosote, record of, Strong. N. Y. Med. Times, Dec., 1889.
Case of tubal pregnancy treated successfully by electrical fœticide, G. M. Edebohls. Med. Rec., Dec. 7, 1889.
Catarrhal neuralgia, A. G. Hobbs. *Ibid.*
Case of cerebral tumour successfully removed by trephining, R. Parker. British Med. Jour., Nov. 30, 1889.
Consecutive cases of abdominal section, Mayo Robson. *Ibid.*
Case of mania transitoria, Bell. Ther. Gaz., Nov. 15, '89.
Duration of contagion in scarlet fever, Wood. Therap. Gaz., Nov.,15, 1889.
Delirium tremens, Johnson. Southern Clinic, Dec., 1889.
Dermatitis papillares, Heitzmann. Jour. Cutan. and Genito-Urinary Diseases, Dec., 1889.
Dürfen syphilitisch-infizirte Aerzte ihre ärztliche Thätigkeit fortsetzen? Neisser–Breslau. Deutsche Medizinal-Zeitung, 21 Nov., 1889.
Die temporäre Resektion des Schädeldaches on Stelle der Trepanation, Wagner. Centralblatt f. Chirurgie, 23 Nov., 1889.
Du rôle de la bacteriologie dans la clinique, Jaccond. La France Méd., Nov. 26, 1889.
Ears, examining in troublesome coughs, Palmer. N. C. Med. Jour., Nov., 1889.
Etiology and prophylaxis of typhoid fever, Fuller. Brooklyn Med. Jour., Dec., 1889.
Elastic ligature, in rectal fistulæ, Crowell. Brooklyn Med. Jour., Dec., 1889.
Experimental research as to actionof natural and artificial salicylic acids and their salts of sodium, Charteris and Maclennan. Brit. Med. Jour , Nov. 30, 1889.
Fibroma diffusum of the labia minora, Collyer. Amer. Jour. of Obstetrics, Dec., 1889.
Gynæcology and abdominal surgery, some practical points in, Walker. Can. Pract., Nov. 16, 1889.
Hæmatoma of sterno-mastoid in infants, Macdonald. *Ibid.*
Herpes Zoster, clinical notes on, Greenough. Boston Med. and Surg. Journal, Dec. 5, 1889.
Hypodermic use of mercurials in the treatment of syphilis, L. Wolff. Therap. Gaz., Nov. 15, 1889.
Intestinal diseases of children during hot weather, Hooper. Jour. Amer. Med. Ass'n, Dec. 7, 1889.
Impaired vision as the result of sunstroke, Baker. Journal Amer. Med. Ass'n, Dec. 7, 1889.
Introduction to a discussion on placenta prævia, J. Braxton Hicks. British Med. Jour., Nov. 30, 1889.
Influence of opium on uric acid, in health and disease, Haig. Br. Med. Jour., Nov. 30,1889.
Laboratorio di bacteriologia e microscopia della direzione di sanita publica, Storza e Caporaso. Gior. Med., Ott., 1889.
La controestensione combinata colla sospensione in un caso di sciatica, Gottardi. *Ibid.*
Lupus erythematosus, a case of, presenting unusual complications, Hardaway. Jour. Cut. and Gen.-Ur. Dis., Dec., 1889.
Mycosis fongoïde of Alibert, Blanc. Jour. Cut. and Gen.-Urin. Dis., Dec., 1889.
Notes on Hoang-Nan, Shoemaker. Ther. Gaz., Nov. 15, 1889.
One cause of typhoid Parker. Med. Record, Dec. 7, 1889.
Pemphigus foliaceus (Cazenave), relapse, *Ibid.*
Purulent peritonitis, Jewett. N. C. Med. Journal. Nov., 1889.
Pus accumulations in the female pelvis, the origin and treatment of, Ashby. Maryland Med. Jour., Nov., 1889.
Perityphlitis, treatment, Allen. Cleve. Med. Gaz., Nov., 1889.
Physical education, McKenzie. Canada Lancet, Dec., 1889.
Primary cancer of the gall-bladder and bile-ducts, Musser. Bost. Med. and Surg. Jour., Dec. 5, 1889.
Peritonite suraiguë au cours d'une double pyosalfingite blennorrhagique latente, Thiroloix. La France Méd., Nov. 28, '89.
Puerperal convulsions, E. P. Hind. Ther. Gaz., Nov. 15, 1889.
Position after delivery as a cause of uterine displacements, Campbell. Therap. Gaz., Nov. 15, 1889.
Reflex nervous phenomena, due to preputial contractions, Bruce. Canada Lancet, Dec., 1889.
Report of one hundred and eighty-seven cases of midwifery in private practice, Zakrzewska. *Ibid.*
Some clinical notes on the work of M. Apostoli, Hobart. Boston Med. and Surg. Journal, Nov. 28, 1889.
The American Academy of Medicine, Connor. Jour. Amer. Med. Ass'n, Nov. 30, 1889.
The possible danger of injury to the middle ear cavity by the use of nasal atomization, Richardson. *Ibid.*
The Morton lecture, Marshall. Lancet, Nov. 23, 1889.
Tubercular peritonitis with tuberculous Fallopian tubes, Ricketts. Amer. Pract. and News, Nov. 23, 1889.
Typhoid spine, Gibney. N. Y. Med. Jour., Nov. 30, 1889.
Typhoid fever, diagnosis, Fuller. Brooklyn Med. Jour., Dec., 1889.
Typhoid fever, treatment of, McCorkle. *Ibid.*
Typhoid fever, complications and sequelæ of, Madden. *Ibid.*
The national formulary and some of its oddities, which are easily overlooked, Stevens. Brookl. Med. Jour., Dec., 1889.
Uterine treatment, the abuse of, through mistaken diagnosis, Goodell. Med. News, Dec. 7. 1889.
Ueber die klinische Bedeutung des Erythema nodosum und verwandter Hautausschläge, Bäumler. Internat. Klinische Rundschau, 27 Oct., 1889.
Uterine fibroids, Prentiss. Amer. Jour. Obstetrics, Dec., 1889.
Uterine canal, of eighty cases of rapid dilatation for dysmenorrhea and sterility. Townsend. *Ibid.*
Uterine fibroids, instance of failure in the treatment of, by electricity, Apostoli. Med. Age, Nov. 28, 1889.
Vital and medical statistics, Billings. Med. Rec., Nov. 30, 1889. (Lecture II), *Ibid.*, Dec. 7, 1889.
Vicarious hemorrhage, Ker· Ocid. Med· Times, Dec., 1889.
Vaginal hysterectomy for cancer, Reed. Cinc. Lancet-Clinic, Dec. 7, 1889.
Vaginal hysterectomy recovery, Sataw. Sei-i-kwai Med. Jour., Sept., 1889.
Wann und in welchem Umfange ist die lokale Behandlung von Nasen- und Halskrankheiten in Badeorten indizirt? Haupt. Deutsche Med. Ztg., 21 Oct., 1889.
Welches Stethoskop soll der Arzt gebrauchen? Pel. Berliner Klin. Wochenschrift, 28 Oct., 1889.
What civilization is doing for the human female, Smith. Can. Med. Rec., Nov., 1889.
Wound infection, the bacterial cause of, Renz. N. W. Lancet, Dec. 1, 1889.
Zur Behandlung des Erysipelas migrans (Wanderrose), Rosenthal. *Ibid.*, 21 Oct., 1889.
Zur älteren Geschichte der klinischen Helminthologie, Hubert. Deutsches Archiv, Oct., 1889.
Zunge, über Aktinomykose der, Maydo. Internat. Klinische Rundschau, 20 Oct., 1889.
Zur Genese der Höhlen im Rückenmark, Miura. Archiv für pathol. Anat. u. Physiol. und für Klin. Med., 2 Spt., 1889.
Zur Lehre von der Hetrologie der Entstehungsweise und den Formen der acuten Peritonitis, Pawlowsky. *Ibid.*
Zur Würdigung der Suggestivtherapie, Hirt. Wiener Med. Presse, 10 Nov., 1889.
Zweizeitige Inzision eines Leberechinokokkus, Hendenreich, Nancy. Deutsche Med. Zeit., 21 Nov., 1889.

INDEX FOR 1889.

ADDRESSES.

Argument for commutation of sentence. Case of People *vs.* Sarah J. Whiteling, Alice Bennett, M.D., 265
Introductory address, J. M. Anders, 529
Ninth inaugural address, Clark Bell, 217
Opening of Medico - Chirurgical and Philadelphia Dental College, 1889
Some phases of cancer, T. A. Reamy, 313
Valedictory address to graduating class of Medico-Chirurgical College, James E. Garretson, A.M., M.D., 317

CLINICAL LECTURES.

Amputation of thigh for elephantiasis arabum, J. W. Croskey, M.D., 553
Artificial fecundation and position during coition, Dr. Luteaud, Paris, 1
Chorea, L. H Mettler, A.M., M.D., 172
Chronic lead poisoning, William F. Waugh, M.D., 799
Clinical lecture, F. S. Dennis, M.D., 697
Thomas G. Morton, M.D., 673
Charles K. Mills, M.D., 745
William Murrell, M.D., F.R.C., 721
Epilepsy, L. H. Mettler, A.M., M.D., 241
Feeding of children, S. S. Stryker, M.D., 193
Gastric carcinoma, Jas. Tyson, M.D., 169
Granular lids—enucleation of ball, Peter D. Keyser, M.D., 769
Heart disease, John Aulde, M.D., 363
Hemiplegia, Wharton Sinkler, M.D., 49
Indigestion. Chorea. Endocarditis, J. M. Anders, M.D., 823
Locomotor ataxia treated by suspension. Clinical lecture of Prof. Charcot, 292
Medical clinic, W. F. Waugh, M.D., 625
Frank Woodbury, A.M., M.D., 289
Mitral Regurgitation. Angina Pectoris, James B. Walker, M.D., 145
Neuritis, Wharton Sinkler, M.D., 289
Newer treatment of diseases of nervous system, Dujardin-Beaumetz, 121
Pyo-nephrosis—rupture of kidney—carcinoma, Charles McBurney, M.D., 771
Surgical clinic, H.E. Goodman, M.D., 337
J. William White, M.D., 364
Syringomyelia, M. Dejerine, 265
Tar and apomorphine in the treatment of winter cough, William Murrell, M.D., F.R.C.P., London, 169
Treatment of urethral strictures by electrolysis, Robert Newman, M.D., 337
Varicocele, G. Frank Lydston, M. D. Part I, 409. Part II, 433

ORIGINAL ARTICLES.

Abscess of spleen—the result of injury, William P. Fleming, M.D., 201
Accidental complications of typhoid fever, Cassius D. Wescott, M.D., 296
Acute pneumonia, E. B. Crone, M.D., 463
Wm. Porter, M.D., 320
Antipyretics, analgesics, and hypnotics, I. N. Love, M.D., 606
Antiseptic surgery in the country, John B. Wheeler, M.D., 702
Atrophy, hypertrophy, and deviation of septum, C. H. Von Klein, M.D., 699
Auto-infection—illustrative cases, John J. Berry, M.D., 201
inoculation in tuberculosis, Lawrence F. Flick, M.D., 3.
Bright's disease without urinary symptoms, W. W. Knight, M.D., 559
Cactus grandiflorus, C. L. Gregory, M.D., 367
Can a doctor make a living without advertising? F. E. Stewart, M.D., 220
Case in which croton oil liniment was accidentally applied to the eyes, a, David Webster, M.D., 30
Case of abnormal development, W. D. Bidwell, A.M., M.D., 4
worth, Kan., 4
Case of Dr. Brown-Sequard, the, John V. Shoemaker, A.M., M.D., 725
Case of enormous fibro-cystic tumor of the uterus. Laparotomy—recovery, X. O. Werder, M.D., 558
Case of extensive brain lesions with ill-defined symptoms, J. J. Berry, M.D. 441
Case of laparotomy for extra-uterine pregnancy, X. O. Werder, M.D., 30
of old fracture of the patella cured by wiring the fragments, W. C. Wile, A. M., M.D., 417
of renal calculus, Ernest B. Sangree, A.M., M.D., 829
Causes of acquired insanity, Joseph Jones, M.D., 457
Cerebro-spinal meningitis, F. T. Kidder, M.D., 29
Chloroform in labor, I. N. Love, M.D., 347
Clinical notes, Wm. B. Atkinson, M.D., 325
observations on effects of direct and indirect traumatisms of the brain, R. Harvey Reed, M.D., 385
Clinical uses of electricity, John V. Shoemaker, A.M., M.D., 411.
Cocaine in hemorrhagic fever, N. P. Hackett, M.D., 156
in urethral surgery, Martin Rively, M.D., 251
Comparative study of common forms of convulsions, Archibald Church, M.D., 601
Compound comminuted fracture of ulna at the elbow joint, P. N. Barker, M.D., 176
Concealed menstruation from imperforate hymen, Cheves Bevill, M.D., 176
Congenital absence of a portion of the anterior abdominal wall, J. M. Barton, M.D., 175
Constipation, Wm. F. Waugh, M.D., 679
cause and treatment, A. W. McKinney, M.D., 100.
Criminal responsibility in narcomania, Norman Kerr, M.D., F.L.S., 751
Cure for constipation, S. Benton, 298
Cure of crooked and otherwise deformed noses, John B. Roberts, M.D., 194
Curse of schools, Walter D. Bidwell, A.M., M.D. (Harvard), 484
Defence of electrolysis in urethral strictures, with documentary evidence, Robert Newman, M.D., 1
Dietetics, J. F. McLaughlin, M.D., 269, 313
Dietetic treatment of patients after abdominal operations, E. E. Montgomery, M.D., 246
Digital divulsion of pylorus for cicatricial stenosis, J. M. Barton, M D., 73
Diphtheria, J. R. Powell, M.D., 28
J. A. De Armond, M.D., 200
J. T. Potter, M.D., 369
G. Herbert Davis, M.D., 488
Disease of inebriety, Edward C. Mann, M.D., 52, 73, 104
Disease of Shrapnell's membranes, Arthur Hartmann, M.D., 366
Double amputations—complications, A. P. Frick, U. S. A., 440
Dyspepsia and anorexia cured by static insulation, H. Montague, M.D., 199
Electricity in gynecology, G. Apostoli, M.D., Paris, France, 49
W. H. Walling, M.D., 172
in the removal of superfluous hairs, Frederick W. Oliver, M.D., 273
in skin and venereal diseases, John V. Shoemaker, A.M., M.D., 534
Electrolysis for the removal of superfluous hairs, H. Montague, M.D., 52
in morbid alterations that are produced in the prostate by gonorrhœa of the urethra, John D. S. Davis, M.D., 25
Enormious multilocular ovarian cyst successfully removed, W. S. Stewart, M.D., 5
Enucleation of tuberculous glands, Thos. W. Kay, M.D., 121
Enumeration of the blood corpuscles, Samuel Wolfe, M.D., 728
Epicystic surgical fistula for cystoscopic exploration, J. D. S. Davis, M.D., 27
Erysipelas of the larynx, Max Thorner, M.D., 174
Experience in intubation, L. Ott, M.D., 123
Facial erysipelas complicating a varicose ulcer of the foot, W. A. N. Dorland, A.M., M.D., 775
Fatal case of double phlegmasia dolens, with remarks on the nature of the disease, A. K. Bond, M.D., 247
Feeding of puerperal convalescents, Charles Meigs Wilson, M.D., 244
Fermentation — its cause and effects, Ernest Laplace, A.M., M.D., 748
Few cases of maternal impressions transferred to offspring, S. T. Straley, M. D., 57
Food in treatment of pulmonary consumption, S. Solis-Cohen, M.D., 248
Four narrow escapes from death from hyper-anæsthesia, at surgical operations, Llewellyn Eliot, M.D., 176
Future of medicine, Wm. T. Plant, M.D., 436
Glyceritum pepsini vitulini, Frank Woodbury, M.D., 249
Habitual constipation in women and its effects, S. J. Wimmer, M.A., M.D., 630
Hæmatoma of the vulva in the non-puerperal state, K. B. Page, M.D., 577
Heroic dose of chloral, A. C. Free, M. D., 678
Hiccough, with notes on treatment. Frederick W. Putnam, M.D., 145
Higher medical education, O. M. Snyder, M.D., 51
Hunting the germ of yellow fever, Frank S. Billings, M.D., 53, 78, 102, 124, 150, 177
Hydriodic acid, J. V. Shoemaker, M.D., 246
Hygiene of pregnancy, Sebastian J. Wimmer, M.A., M.D., 222
Hysterectomy for large fibro-myoma, D. Benjamin, M.D., 153
Hysteria in younger children, Samuel Wolfe, M.D., 148
Importance of careful diagnosis of pregnancy, with the history of a case of retroflexion going to full term, W. S. Stewart, A.M., M.D., 294
Indications for, and limitations of, eperation for removal of the uterine appendages, E E. Montgomery, M.D., 315
Influence of medical journals on march of science, T. D. Crothers, M.D., 317
Instances of the hereditary influence in the causation of multiple pregnancy, Charles Meigs Wilson, M.D., 829
Insufficiencies of the ocular muscles and their treatment with prisms and by graduated tenotomies, Read Jennings McKay, M.D., 627, 651
Jugulation of acute diseases, L. A. Merriam, M.D., 367
Kemmler case, T. D. Crothers, M.D., 608
Large nævus of the forearm—treatment, A. C. W. Beecher, M.D., 320

Luxation of the fourth cervical vertebra resulting in hemiplegia. Reduction and cure, Ernest Laplace, M.D., 582
Malarial pneumonia, J. P. Francez, M. D., 345
Man and his development, Dr. Thomas J. Moore, 507
Measles in the second week of infancy, T. Ridgway Barker, M.D., 680
Mechanical writing in the prevention and cure of writer's cramp and allied disorders, W. R. D. Blackwood, M.D., 365
Medico-legal cases, Henry A. Riley, Esq., 25, 583
Mode of entrance of the bacillus tuberculosis into the system, Lawrence F. Flick, M.D., 579
Nasal cavities, E. E. Hamilton, M.D., 365
Nature of urethral fever, Edward M. Ground, M.D., 393
New ano-rectal speculum, Robert W. Martin, M.D., 537
Name proposed for the ventricular bands, Ephraim Cutter, M.D., LL.D., 462
Notes on a case of nasal caries, complicated with meningitis, successfully treated by means of the surgical drill, Wm. C. Jarvis, M.D., 98
on certain symptoms of typhoid fever, George A. Hewitt, M.D., 128
Observations in clinical therapeutics, J. A. Robison, M.D., 387
Operation for opaque staphyloma, M. M. Mitivier, M.D., 250
Opium addiction, W. S. Watson, M.D., 267
Overcrowding, J. M. Anders, M.D., 150
Paracentesis in internal hydrocephalus, Samuel Ayres, M.D., 269
Personal reminiscences on the subject of anæsthesia, H. Culbertson, M.D., 147
Phlebitis, A. R. Smart, M.D., 361
Phthisis and its natural cure, John A. Lanigan, M. D., 202, 249
Physiological morality. A contribution to social science and preventive medicine, Frank S. Billings, M.D., 343, 368, 389, 6
Physiology of digestion—the nutritive organization, W. Wood, M.D., 241
Pneumonia; a method of cure, Enos. T. Blackwell, M.D., 385
Prerequisites to marriage and laws to enforce them, E. L. Detweiler, M.D., 80
Principles that should guide us in the rational treatment of gonorrhœa, Bransford Lewis, M.D., 505
Problem of infant feeding, I. N. Love, M.D., 250
Proper food of infancy and childhood, B. F. Hart, M.D., 291
Proper use of ergot in labor, F. O. Donoghue, M.D., 655
Pulmonary hygiene, J. G. Mays, M.D., 338
Rational treatment for diphtheria, A. E. Hoadley, M.D., 800
Recent medical cases, Henry A. Riley, Esq., 321, 416
Relation of education to insanity, Geo. D. Stahley, A.M., M.D., 178, 193
Removal of epiphyseal exostosis of humerus, James B. Hungate, M.D., 101
Renal disease of scarlatina, W. M. Welch, M.D., 825
Report of eighteen cases of inflammation of the breast, Elizabeth M. Farrand, M.D., 197
on cases of the Alexander operation, D. T. Gilliam, M.D., 222
on progress of electro-therapeutics, W. R. D. Blackwood, M.D., 125
of the special committee on diseases of the alimentary canal, A. J. Baxter, M.D., 392
Review of cases of tuberculosis, Lawrence F. Flick, M.D., 97
Review of progress in medical and surgical electricity, William R. D. Blackwood, M.D., 295, 773
Rheumatic pericarditis, Joseph M. Patton, M.D., 555
Secondary perineorraphy, E. J. Kempf, M.D., 271
Simultaneous amputation of both arms —recovery, W. W. Keen, M.D., 30
Sodium silico-fluoride, J. W. Croskey, M.D., 217
Some observations on the proper form of a bougie, M. Rively, M.D., 512
points on piles, William R. D. Blackwood, M.D., 246
Splenic fever, B. F. Lamb, M.D., 344
Stricture of the urethra, W. A. Proctor, M.D., 272
Studies on alcohol, E. Chenery, M.D., 7, 31, 57, 80
Suction for elevating depressed and fractured bones of cranium, extraction of bullets, and other purposes, George J. Ziegler, M.D., 6
Surgical dressings, C. W. Brown, M.D., 481
shock—its pathology and treatment, Henry Jarrett, M.D., 806
Suspension in locomotor ataxia, R. A. Kinloch, M.D., 415
Tablet triturates, Ephraim Cutter, M.D., LL.D., 177
Time element in office practice, F. W. Higgins, M.D., 460
Training of nurses, Hal C. Wyman, M.S., M.D., 106
Treatment of chronic nasal catarrh, C. F. McGahan, M.D., 649
of neuralgia, E. P. Hurd, M. D., 675
of uterine fibroids by Apostoli's method–intrauterine electrolysis, Delétang, M.D., 6
Treatment of intestinal obstruction, J. M. Baldy, M.D., 101
Two cases of removal of spontaneous dislocated lenses from the anterior chamber of the eye, Peter D. Keyser, M.D., 124
Unique presentation of a fœtus, E. P. Bernardy, M.D., 52
Use of quinia in labor, Daniel Strock, M.D., 323
Vinegar and vinegar yeasts, E. & J. A. Cutter, 272
What is the doctor's duty to his patient suffering with maliguant disease? Wm. W. Parker, M.D., 77
not to do, and what to do in the treatment of malarial fever, B. O. Kiester, M.D., 152
Window in typhoid fever, A. K. Minich, M.D., 156

HYDROTHERAPEUTICS.

S. Baruch, M.D.:

Contra-indications to cold bath treatment of typhoid fever, 610
Hydrotherapeutics, 632
Hydrotherapy in typhoid fever, 441
Plea for the practical utilization of hydrotherapy, 729, 753, 776, 807, 830
Queries and objections answered. Contra-indications considered, 514
Rationale of technique in fevers, 561
Technique in acute cases, 464

THE POLYCLINIC.

Cooper Hospital:
Concussion of spine, Godfrey, 223
Dislocation of the spine, Godfrey, 252
Paralysis following injuries to the spine, Godfrey, 204
Jefferson Hospital:
Abscess from ligature, Barton, 323
of the right breast, Barton, 375
of tibia, Barton, 299
Boils, Allis, 128
Chancre, Hearn, 128
Cystotomy, Nancrede, 298
Hemorrhoids, Nancrede, 346
Hare-lip, Allis, 127 Nancrede, 346
Hip disease—enforced recumbency, Allis, 204
Hip-joint disease—a point in diagnosis, Allis, 204
Hydrocele, Allis, 127
Osteotomy, Nancrede, 299
Prospective digital divulsion, Barton, 299
Removal of astragalus, Barton, 323
Salivary calculus, Nancrede, 299
Wiring a fracture, Barton, 299
Manhattan General Hospital, New York:
Acute endocarditis—hydrotherapeutic treatment, Baruch, 418
Subacute rheumatism treated hydrotherapeutically, Baruch, 418
Medico-Chirurgical Hospital:
Abscess of cheek, Stubbs, 394
Acne rosacea, Shoemaker, 154
Acute pleurisy, Waugh, 56
Albuminuria in pregnancy, Stewart, 395
Arthritis, Pancoast, 128
Asthma with spinal curvature, Woodbury, 32
Astigmatism, Fisher, 750
Auto-intoxication, Waugh, 179
Bacillus tuberculosis in sputa, Laplace, 756
Blood stasis, Pancoast, 178
Brazilian bean, Shoemaker, 178
Care of the new-born, Keyser, 83
Cerebral syphilis, Waugh, 33
Chancroids, Stubbs, 84
Chorea, Anders, 489, 584
Chronic catarrhal pneumonia, Woodbury, 31
Cicatrix of cornea, Keyser, 83
Collyria, Keyser, 128
Consumption, Woodbury, 395
